50
51 **Abstract**
52 Italy has a rich natural heritage, which is dangerously under pressure. In recent years, there is an
53 increased awareness of the crucial role of plants in ecosystem functioning and in providing ecosystem
54 services. Consequently, an updated Red List of the Italian vascular flora was compiled in this work,
55 at the request of the Ministry for Environment, Land and Sea Protection, with the scientific support
56 of the Italian Botanical Society. The IUCN Red List criteria were applied to 2,430 Italian native
57 vascular plant taxa to assess their current extinction risk and to highlight the major threats affecting

58 the Italian flora. Our results revealed that 54 taxa (2.2% of the assessed taxa) are extinct or possibly
59 extinct at regional level, while 590 taxa (24.3%) were assigned to a risk category. Moreover, 404 taxa
60 (16.6%) were categorized as Data Deficient. The Italian vascular flora is primarily threatened by
61 habitat modifications due to anthropic disturbance and, especially, to agriculture, tourism and
62 residential development. Coastal areas and lowlands, where anthropogenic impacts and ecosystem
63 destruction are more pronounced, host the greatest number of extinct or declining taxa. Our results
64 represent an important baseline to establish conservation priorities, legislative choices and
65 intervention strategies on a national scale.

66

67

68 **Introduction**

69 One of the main goals of Conservation Biology is to avoid extinctions and to reduce rates of species
70 decline. Due to the large amount of threatened taxa, this requires an estimation of the species
71 extinction risk in order to identify taxa, and geographical areas that are prioritary for conservation
72 (Possingham et al. 2002; Isaac et al. 2007; Carta et al. 2019). Current understanding of ongoing
73 extinction comes primarily from projections or assessments of extinction risk (Brummitt et al. 2015;
74 Humphreys et al. 2019). The IUCN Red Lists of Threatened Species are widely recognized as the
75 most authoritative information source on the extinction risk of species, because they use a
76 standardized set of quantitative criteria for assessing species conservation status and threats (Maes et
77 al. 2015; Collen et al. 2016). The application of the IUCN Red List categories and criteria allows the
78 production of Red Lists, which are widely recognized as valuable tools in nature conservation
79 programmes (IUCN 2017). For instance, up-to-date Red Lists are fundamental starting points for
80 conservation actions as they provide useful information to support prioritization procedures of
81 conservation emergencies, and to monitor changes in the conservation status of species (Moreno Saiz
82 et al. 2015). Moreover, although Red Lists cannot be considered policy prescriptive, they represent
83 a valid tool (if not the only one available) to highlight the presence of threatened plant species in
84 Natura 2000 sites Standard Data Forms.

85 Although in several countries the priority of up-to-date Red Lists has been addressed since a long
86 time, the urgency of compiling Red Lists has long been underestimated in Italy.

87 The first Italian red data book included vascular plants, bryophytes and lichens (Conti et al. 1992). It
88 listed 458 vascular plants, representing 5.6% of the Italian native vascular flora.

89 This first contribution was followed by revisions, limited to vascular plants, at national and regional
90 levels (Conti et al. 1997; Pignatti et al. 2001). These Red Lists stimulated Italian botanists to

91 investigate rare and declining plants. As a major outcome, after a few years, several species
92 considered to be extinct in Italy were rediscovered. These include *Brassica procumbens* (Poir.)
93 O.E.Schulz (Baldini 1998), *Gagea spathacea* (Hayne) Salisb. (Delfini et al. 2005), and *Trifolium*
94 *latinum* Sebast. (Fanelli et al. 2012). Additionally, the publication of national checklists (Conti et al.
95 2005; Bartolucci, Peruzzi, et al. 2018) substantially improved the knowledge on the Italian flora since
96 the first version of the Red List was published. Such checklists incorporated the latest taxonomic
97 updates, along with a large amount of floristic and taxonomic novelties published in regional and
98 local floras, and in the scientific reports published by the working group for Floristics, Systematics
99 and Evolution of the Italian Botanical Society (Bartolucci et al. 2016; Bartolucci, Peruzzi, et al. 2018;
100 Bartolucci, Domina, Ardenghi, Banfi, et al. 2018, Bartolucci, Domina, Ardenghi, Bacchetta, et al.
101 2018; Bartolucci et al. 2019). Therefore, new data concerning the diversity of the Italian vascular
102 flora highlighted the need to update the existing Italian Red Lists of vascular plants. This urgency is
103 emphasized by the fact that such Red Lists were compiled based on an older version of the IUCN red
104 listing protocol, which shows substantial differences from the current IUCN standards (IUCN 2012a).
105 A further boost to a new red listing phase of the Italian flora was given by a series of papers published
106 since 2008 in the journal *Informatore Botanico Italiano* (currently *Italian Botanist*), devoted to the
107 assessment of plant taxa of conservation concern (e.g., Rossi et al. 2008; Fenu et al. 2018, 2019;
108 Orsenigo, Cambria, et al. 2018, Orsenigo et al. 2019).
109 Finally, in 2012 the Italian Ministry for Environment, Land and Sea Protection commissioned the
110 Italian Botanical Society to produce a New Red List of the Italian flora (Rossi et al. 2013; 2014;
111 2020). The present work, coordinated by the working group for Nature Conservation of the Italian
112 Botanical Society, provides and analyses the results of the assessment of 2,430 Italian vascular plant
113 taxa, thus representing the most comprehensive report on the conservation status of the flora of Italy.
114 The information presented here will be a reference for planning conservation actions and for raising
115 public awareness on plant diversity in Italy.

116

117 Materials and methods

118 Species selection and information source

119 The overall target included 2,430 taxa, which were selected according to three criteria: 1) policy
120 species (PS: taxa listed in the annexes of the Habitats Directive 92/43/EEC and Bern Convention)
121 (Rossi et al. 2016; Fenu et al. 2017), 2) taxa endemic to Italy (Peruzzi et al. 2014), and 3) a group of
122 taxa of conservation concern. The latter group encompassed: a) plants occurring in highly threatened
123 habitats (e.g., wetlands and coastal habitats) for which a decline was documented over the last 30

124 years, and b) taxa considered as EX, EW, or CR in the previous Italian Red Lists (Conti et al. 1992,
125 1997).

126 As far as the information source is concerned, in the final dataset we summed up all the risk
127 assessments currently available for the Italian vascular plants. In particular, the assessment data for
128 Italian policy species and Italian endemic taxa were deduced from Rossi et al. (2016) and Orsenigo,
129 Montagnani, et al. (2018), respectively. Further information for other species of conservation concern
130 were obtained from the contributions published since 2008 in the journal Informatore Botanico
131 Italiano (later Italian Botanist). Finally, the dataset was completed by integrating unpublished data
132 for 932 taxa (Table 1).

133

134 *Red listing procedure*

135 The conservation status of the selected taxa was assessed according to the IUCN categories and
136 criteria (IUCN 2012a). Records on species distribution were collected from published and
137 unpublished data, herbarium specimens, and recent field surveys (since the early 2000s onwards). For
138 taxa growing in pristine habitats, such vertical cliffs or remote forests, data since the early 1990s were
139 used. All of the collected records were validated by groups of regional experts (Rossi et al. 2013;
140 2020). The taxonomic nomenclature was updated according to the recent national checklist
141 (Bartolucci, Peruzzi, et al. 2018) and subsequent updates Bartolucci, Domina, Ardenghi, Banfi, et al.
142 2018; Bartolucci, Domina, Ardenghi, Bacchetta, et al. 2018; Bartolucci, et al. 2019). The collection
143 of data on distribution and threats was followed by a preliminary assessment, which underwent a
144 process of peer review during a series of workshops promoted by the working group for Nature
145 Conservation of the Italian Botanical Society (Rossi et al. 2014). Over 100,000 records were
146 processed in QGIS 2.18 (2017). These records were organized into a geo-database including sites of
147 taxon occurrence (a total of 59,887 cells) on a fixed 2_2 km grid (Gargano 2011), population trends,
148 and the main threats at local level identified by means of expert-based observations and literature
149 sources. Threats were classified according to the IUCN threats classification scheme (version 3.2 –
150 IUCN 2012b), and the relative data were used to classify the major threats affecting vascular plants
151 in Italy. The assessments were mostly based on criterion B. However, when reliable data on
152 population size and/or trends were available, other criteria were also applied (i.e. A, C, and D). The
153 grid-based mapping approach allowed for standardizing calculations of Area of Occupancy (AOO),
154 as required under criterion B2 (IUCN 2012a). Following the precautionary approach suggested by
155 Butchart et al. (2006), taxa that were not recorded during the previous three decades, but for which
156 uncertainty regarding extinction remained, were categorized as “Critically Endangered - Possibly

157 Extinct [CR(PE)]”. A taxon was considered extinct (EX) when it was not recorded in the last 50 years,
158 and when recent field surveys focused on finding the taxon in its historical area of occurrence were
159 unsuccessful.

160 Results

161 Red listing

162 Overall, our dataset included the assessment of the extinction risk for 29.7% of the whole Italian
163 vascular flora. Nine taxa (0.4% of the assessed taxa) were categorized as Extinct (EX) or Regionally
164 Extinct (RE) in Italy: *Aldrovanda vesiculosa* L., *Anthyllis hermanniae* L. subsp. *sicula* Brullo &
165 Giusso, *Herniaria fontanesii* Gay subsp. *Empedocleana* (Lojac.) Brullo, *Hieracium tolstoi* Fen. &
166 Zahn, *Limonium catanense* (Tineo ex Lojac.) Brullo, *Ranunculus hostiliensis* Pignatti, *Ranunculus*
167 *mutinensis* Pignatti, *Sonchus palustris* L., *Suaeda kocheri* Guss. ex C.Brullo, Brullo & Giusso. Four
168 taxa (0.2%) were recognized as Extinct in the Wild (EW) in Italy: *Carlina acanthifolia* All. subsp.
169 *utzka* (Hacq.) Meusel & K€astner, *Clematis integrifolia* L., *Limonium intermedium* (Guss.) Brullo,
170 and *Stratiotes aloides* L. The category EW assigned to *L. intermedium* is valid at a global level, since
171 this species is endemic to Italy. Fourty-one taxa (1.7%) were not recorded in recent years and were,
172 thus, qualified as Critically Endangered (Possibly Extinct) [CR(PE)] (Figure 1; Table S1). Overall,
173 590 taxa (24.3%) were assigned to a risk category (Figure 1). Additional 395 taxa (16.2%) qualified
174 as Near Threatened (NT), and 987 (40.6%) as Least Concern (LC). Finally, 404 taxa (16.6%) were
175 considered as Data Deficient (DD), because available data did not allow a reliable assessment.

176

177 **Table 1.** IUCN Red list status and assessment criteria for the Italian vascular flora. For risk category
178 of all Italian endemic taxa see Orsenigo, Montagnani, et al. (2018b). For risk category of Italian policy
179 species see Rossi et al. (2016). Threats follow the IUCN Classification Scheme (version 3.2-IUCN
180 2012b).

181

182 Major threats

183 The most common threat to the Italian vascular flora was “natural system modifications” (39% of the
 184 2,430 taxa), followed by “agriculture and aquaculture” (27%), “residential development” (27%), and
 185 “human disturbance” (20%; Figure 2). Most threats are co-occurring, indicating that many taxa are
 186 subjected to a set of correlated adverse processes (Table S1). For instance, many plants threatened by
 187 tourism and recreational areas development were also threatened by the impact of transport, like roads
 188 and railroads (Table 1). Threats to vascular plants varied among geographical areas. Taxa occurring
 189 in coastal habitats resulted more affected by tourism development and disturbance, while processes
 190 related to residential and commercial development, agriculture, and transportation and service
 191 corridors affected taxa living in the most populated areas, usually in lowlands. Climate change

192 (drought), plant collection for commercial or cultural purposes, and non-native invasive species
193 currently represent minor threats.

194 **Discussion**

195 By summing up pre-existing and unpublished data, this study presents the assessment of 2,430
196 vascular taxa native to Italy, i.e. about 30% of the 8,195 native vascular taxa recorded for Italy
197 (Bartolucci, Peruzzi, et al. 2018). Many other national Red Lists of vascular plants were produced in
198 Europe in the last decade, e.g., in Spain (1,571 taxa assessed - Moreno Saiz 2008) or England (1,859
199 taxa assessed, including all the microspecies of *Hieracium* and *Taraxacum* – Stroh et al. 2014). The
200 Italian Red List presented here is one of the largest and most complete assessments of the vascular
201 flora native to a country in Europe and in the Mediterranean Basin, only recently overtaken by France
202 (4,982 taxa evaluated - IUCN France et al. 2018). The proportion of Italian threatened vascular plant
203 taxa (24.3%) is slightly higher compared to the global estimations (22.0% - Brummitt et al. 2015),
204 and comparable to other European or Mediterranean countries, e.g., England (19.9% - Stroh et al.
205 2014) and Spain (22.1% - Mu~noz-Rodr_iguez et al. 2016), although in the latter country the taxa
206 have been evaluated through a quick assessment process (Mu~noz-Rodr_iguez et al. 2016).
207 Conversely, the rate of threatened vascular plants in Italy is more than double than that of France
208 (9.7% - IUCN France et al. 2018). However, in the latter country, the assessment regarded most of
209 the taxa recorded nationwide and not only those considered of conservation interest. The proportion
210 of threatened taxa in the present extended Red List is even slightly higher (24.3%) than that obtained
211 considering only the Italian endemics (22.4% - Orsenigo, Montagnani, et al. 2018). Once again, this
212 could be explained by the assessment, for the present Red List, of taxa living in highly threatened
213 habitats or with a documented decline in the past years. In recent years, a large amount of information
214 was published about the Italian vascular flora, deriving from field surveys, checklists, floras, and
215 taxonomic revisions. Despite this, about 17% of the taxa assessed herein were categorized as Data
216 Deficient. This suggests a lack of distribution data, limited information on threats, and/or significant
217 gaps in taxonomic knowledge for many taxa. Moreover, the occurrence of 41 taxa was not observed
218 in recent times, so that they were assessed as CR(PE). Consequently, further field, taxonomic,
219 biogeographical, and ecological investigations of the Italian vascular flora should be undertaken to
220 fill these gaps, with special regard to least known areas and groups of species, such as apomictic and
221 poorly known genera. The analysis of threats affecting vascular plants reveals that the anthropic
222 pressure related to land use changes is the main driver of extinction risk. In particular, more than 60%
223 of the assessed taxa are affected by direct and/or indirect human disturbances, like natural system
224 modifications, agriculture, residential and commercial development, recreational activities or
225 transportation and service corridors (Figure 2; Table S1). Many of the extinct or possibly extinct taxa

226 grew in habitats or geographical areas that underwent drastic upheavals in the last decades. Some
227 examples come from the wetlands in the Po Plain (Bolpagni et al. 2018), where some species (e.g.,
228 *Aldrovanda vesiculosa* L., *Pilularia globulifera* L., *Ranunculus hostiensis* Pignatti, etc.) met
229 extinction due to changes in agricultural practices. On the Italian islands, some plants (e.g. *Anthyllis*
230 *hermanniae* L. subsp. *corsica* Brullo & Giusso and *Limonium intermedium* (Guss.) Brullo) underwent
231 extinction because the growing tourist inflow is causing severe impacts on dunal and other coastal
232 habitats (see e.g. Ballantyne and Pickering 2013; Wraith and Pickering 2018). The abandonment of
233 traditional agricultural practices and crops like emmer or flax caused the decline and extinction of
234 some segetal species (Storkey et al. 2012; Perrino and Calabrese 2018): this is the case for *Silene*
235 *linicola* C.C.Gmel. or *Bromus grossus* Desf. ex DC. No threats were recorded for about 20% (484)
236 of the assessed taxa, mainly living in mountain areas, where anthropic pressure is lower.

237 As previously observed (e.g. Fenu et al. 2017; Orsenigo, Montagnani, et al. 2018), some highly-
238 debated threatening factors (e.g. climate change, invasive species) seem to have a negligible impact
239 on the Italian native flora. On a global level, climatic change and alien species are considered two
240 alarming drivers of species extinction (G_omez et al. 2015; Bellard et al. 2016). Nonetheless, only a
241 minor fraction of the assessed Italian taxa results directly affected by such threats.

242 Probably, this incongruence reflects difficulties in quantifying the true impact of these endangering
243 processes due to the lack of reliable assessment methods (Attorre et al. 2018). Our results represent
244 an important baseline to establish conservation priorities, legislative choices, and intervention
245 strategies on a national and regional scale. We recommend scientists and stakeholders to take this
246 information into account in conservation planning, allowing for an optimization of conservation
247 efforts while minimizing conservation costs (Carta et al. 2019). Conservation measures for
248 endangered species, both at legal and practical levels, cannot be further postponed if we truly intend
249 to prevent their extinction and halt the further deterioration of the Italy's biodiversity status.

250 In this study, 2,430 vascular plants native to Italy were assessed under the IUCN categories and
251 criteria, representing about 30% of the 8,195 native vascular flora recorded for Italy (Bartolucci et
252 al., 2018a). Many other examples of national Red lists of vascular plants have been produced in
253 Europe in the last decade, like in Spain (1,571 taxa assessed; Moreno Saiz 2008) or England (1,859
254 taxa assessed, including all the microspecies of *Hieracium* and *Taraxacum*; Stroh et al. 2014).
255 Nevertheless, this Italian Red list is one of the largest and most complete conservation assessments
256 of the vascular flora native to a country in Europe and in the Mediterranean Basin, only recently
257 overtaken by France (4,982 taxa evaluated; UICN France et al., 2018) The proportion of threatened
258 Italian vascular plant taxa (24.3%) is slightly higher compared to the global estimations (22.0%;
259 Brummitt et al., 2015), or to other European or Mediterranean countries, i.e. England (19.9%; Stroh

260 et al. 2014) and Spain (22.1%; Muñoz-Rodríguez et al., 2016), albeit in the latter country the taxa
261 have been evaluated through a quick assessment process (see Muñoz-Rodríguez et al., 2016 for
262 details). Instead, the number of threatened vascular plants in Italy is more than double than France
263 (9.7%; IUCN France et al., 2018), however in the latter country most of the taxa recorded for national
264 territory were assessed, beyond those considered of conservation interest. Also considering the only
265 Italian endemic plant taxa (Orsenigo et al. 2018b), the proportion of threatened taxa is slightly higher
266 in this extended red list (22.4% vs 24.3%). Once again this could be explained by the species selection
267 method that in the extended red list incorporates species living in highly threatened habitats or with
268 a documented decline in the past years.

269 Although, in recent years, field explorations, checklists, regional floras and taxonomic reviews on the
270 Italian flora have been increasingly published, about 17% of vascular plants have been categorized
271 as Data Deficient, indicating that for many taxa the distribution data are lacking and/or they show
272 significant gaps of taxonomic knowledge. Moreover, 41 taxa have not been confirmed in recent times
273 and have been listed as CR(PE). Consequently, further field, taxonomic, biogeographical, and
274 ecological investigations of Italian plant species should be undertaken to fill these gaps of knowledge,
275 especially for less known areas and group of species like apomictic and poorly known genera.
276 The analysis of threats affecting vascular plants reveals that the anthropic pressure connected with
277 land use changes is the main driver of extinction risk. In particular, more than 60% of the assessed
278 species show an impact referable to human direct and/or indirect disturbance like natural system
279 modification, agriculture, residential and commercial development, recreational activities or
280 transportation and service corridors (Figure 2; Table S1). Many of the extinct or possibly extinct taxa
281 grew in habitats or geographical areas that have undergone upheavals in the last decades leading to
282 negative impacts on the vascular flora: examples come from wetlands in Po Plain where agricultural
283 practices radically changed (e.g., *Aldrovanda vesiculosa* L.; *Pilularia globulifera* L.; *Ranunculus*
284 *hostiliensis* Pignatti etc.) or sandy dunes and coastal areas in major and minor islands (e.g. *Anthyllis*
285 *hermanniae* L. subsp. *corsica* Brullo & Giusso; *Limonium intermedium* (Guss.) Brullo), where tourist
286 inflow often grew up massively (e.g., Ballantyne and Pickering, 2013). Also the abandonment of
287 traditional agricultural practices and crops like emmer or flax have caused the decline and extinction
288 of some species strictly dependent by them, like *Silene linicola* C.C.Gmel. or *Bromus grossus* Desf.
289 ex DC. Threats were not recorded for about 20% (484 taxa) of the assessed species.

290 Our results represent an important baseline to establish conservation priorities, legislative choices
291 and intervention strategies at the national scale. We recommend scientists and stakeholders to take
292 this information into account in conservation planning, allowing for an optimisation of conservation
293 efforts while minimizing conservation costs (Carta et al. 2019). Conservation measures for

294 endangered species, both at normative and practical level, cannot be further postponed in order to
295 prevent their extinction and halt the worsening of biodiversity status.

296

297 **Acknowledgements**

298 We gratefully acknowledge more than 300 Italian botanists who provided field and unpublished data,
299 without whose collaboration these assessments would have been impossible.

300

301 **Disclosure statement**

302 No potential conflict of interest was reported by the author(s).

303

304 **Funding**

305 The authors are grateful to the Italian Ministry for the Environment, Protection of Land, and Sea,
306 General Directorate Protection of Nature and Sea, for its financial support of the Plant Red List
307 Assessment Program, and to the Secretariat of the Italian Botanical Society for its support during the
308 process.
