3 **Abstract**  
4

5 The direct synthesis and consolidation by SPS (1950°C, 20min, 20MPa) of high-entropy  
6  
7  $(\text{Hf}_{0.2}\text{Mo}_{0.2}\text{Zr}_{0.2}\text{Nb}_{0.2}\text{Ti}_{0.2})\text{B}_2$  from elemental powders resulted in a multiphase product. An increase of  
8  
9 the heating rate determined a change of the mechanism governing the synthesis reaction from gradual  
10  
11 solid-state diffusion to rapid combustion regime, while the final conversion degree was 67wt.%. The  
12  
13 sintered product displayed a non-uniform microstructure with the presence of 10-15 $\mu\text{m}$  sized pores, due  
14  
15 to volatilization phenomena occurring during the combustion synthesis reaction. In contrast, when the  
16  
17 SPS process was preceded by powder synthesis via SHS, a homogeneous single-phase ceramic was  
18  
19 obtained. Clear benefits are derived by the use of SHS, able to provide very shortly powders with  
20  
21 elemental species very well intermixed, so that the obtainment of  $(\text{Hf}_{0.2}\text{Mo}_{0.2}\text{Zr}_{0.2}\text{Nb}_{0.2}\text{Ti}_{0.2})\text{B}_2$  during the  
22  
23 subsequent SPS stage is strongly promoted. The resulting 92.5% dense product shows superior oxidation  
24  
25 resistance with respect to individual borides prepared with the same method.

2  
3 **1. Introduction**  
4

5 Due to their recent discovery and the huge potential they might provide in several emerging or  
6 traditional application areas, high-entropy (HE) ceramics have immediately gained a significant  
7 attention of the scientific community from both the experimental and theoretical points of view [1-27].  
8  
9

10  
11 As for the general class of high-entropy alloys, HE ceramics are the result of the combination of  
12 different (at least four) individual constituents in near-equimolar percentages, where metal cations are  
13 incorporated into the lattice to generate single-phase crystalline solid solutions with maximum  
14 configurational entropy [28,29]. The corresponding decrease of the Gibbs free energy makes the  
15 resulting material thermodynamically more stable at high temperatures. Besides the intrinsic interest for  
16 such novel ceramic's family, different studies have reported that members of HE materials exhibit  
17 superior hardness [4,5,9,10,16], elastic modulus [10] and oxidation resistance [4,23] properties as  
18 compared to the individual binary constituents.  
19

25  
26  
27  
28  
29  
30

31  
32 The HE ceramic systems investigated so far include different oxides [1-3,7,8,12,17], carbides  
33 [5,6,10,12,16,23-27], borides [4,9,11,14,18,20-22], and silicides [15,19]. These studies are mostly  
34 devoted to the fabrication and characterization of these materials in bulk form, although few  
35 investigations are also specifically dedicated to the obtainment of HE ceramics as powders [13,18,27],  
36 or films [9]. In this context, Spark Plasma Sintering (SPS) has been largely considered for the  
37 preparation of massive bodies, due to the well know advantages associated to this technology [30,31].  
38  
39  
40  
41  
42  
43  
44  
45

46 The first study available in the literature on the synthesis of High-Entropy Borides (HEBs) was  
47 conducted by Gild and co-workers at the University of California, San Diego (USA) [4]. In the latter  
48 work, six different five-components HEBs were prepared via a double-stage process. The corresponding  
49 metal diborides ( $ZrB_2$ ,  $HfB_2$ ,  $TaB_2$ ,  $TiB_2$ ,  $MoB_2$ ,  $NbB_2$ , and  $CrB_2$ ) were first co-milled in equimolar  
50 proportions and the resulting powders consolidated for 5 min by SPS at 2000°C under an applied  
51 pressure of 30 MPa. The final samples displayed relative densities up to about 92.4%, with superior

1  
2  
3 hardness and oxidation resistance properties with respect to the individual components processed under  
4  
5 the same conditions. The contamination of some oxides was also reported to occur in most of the  
6  
7 processed materials, for instance when considering  $(\text{Hf}_{0.2}\text{Mo}_{0.2}\text{Zr}_{0.2}\text{Nb}_{0.2}\text{Ti}_{0.2})\text{B}_2$ . More recently, the  
8  
9 same group of authors proposed an alternative two-stage process for the preparation of  
10  
11  $(\text{Hf}_{0.2}\text{Zr}_{0.2}\text{Ta}_{0.2}\text{Nb}_{0.2}\text{Ti}_{0.2})\text{B}_2$  [14]. The initial powders were first pre-sintered for 5 min at 1600°C and  
12  
13 30MPa and the resulting compact was processed by Flash-SPS with no die, using different electric  
14  
15 power conditions (from 30 to 100% of the maximum level provided by their equipment). The addition of  
16  
17 3 wt.% graphite to the initial mixture was reported to reduce oxides content and improve product density  
18  
19 up to 99.3% of the theoretical level, being the latter one evaluated by assuming no loss of carbon during  
20  
21 sintering. The obtained material consisted of the single hexagonal diboride phase along with small  
22  
23 amounts of cubic carbide phase, formed due to graphite addition.  
24  
25  
26  
27  
28

29  
30 The fabrication of dense  $(\text{Hf}_{0.2}\text{Zr}_{0.2}\text{Ta}_{0.2}\text{Cr}_{0.2}\text{Ti}_{0.2})\text{B}_2$ ,  $(\text{Hf}_{0.2}\text{Mo}_{0.2}\text{Zr}_{0.2}\text{Nb}_{0.2}\text{Ti}_{0.2})\text{B}_2$ , and  
31  
32  $(\text{Hf}_{0.2}\text{Mo}_{0.2}\text{Ta}_{0.2}\text{Nb}_{0.2}\text{Ti}_{0.2})\text{B}_2$  was very recently accomplished by **Zhang et al. [21]**. Mixtures of  
33  
34 transition metal oxides ( $\text{HfO}_2$ ,  $\text{ZrO}_2$ ,  $\text{TaO}_2$ , etc.) and boron were first heat treated for 1h at 1600°C in  
35  
36 vacuum, and the resulting product was processed in Argon by SPS for 10 min at 2000°C, and 30MPa.  
37  
38 The resulting materials displayed relative densities above 95.5%, although the compositional  
39  
40 homogeneity was not fully reached, particularly when considering the  $(\text{Hf}_{0.2}\text{Mo}_{0.2}\text{Zr}_{0.2}\text{Nb}_{0.2}\text{Ti}_{0.2})\text{B}_2$ , and  
41  
42  $(\text{Hf}_{0.2}\text{Mo}_{0.2}\text{Ta}_{0.2}\text{Nb}_{0.2}\text{Ti}_{0.2})\text{B}_2$  systems. The fabrication of  $(\text{Hf}_{0.2}\text{Zr}_{0.2}\text{Ta}_{0.2}\text{Nb}_{0.2}\text{Ti}_{0.2})\text{B}_2$ ,  
43  
44  $(\text{Hf}_{0.2}\text{Zr}_{0.2}\text{Mo}_{0.2}\text{Nb}_{0.2}\text{Ti}_{0.2})\text{B}_2$ , and  $(\text{Hf}_{0.2}\text{Mo}_{0.2}\text{Ta}_{0.2}\text{Nb}_{0.2}\text{Ti}_{0.2})\text{B}_2$  was also investigated by the same authors  
45  
46 using  $\text{B}_4\text{C}$  and C as reducing agents instead of B [22]. The materials obtained after SPS were reported to  
47  
48 display relative densities of 96.3, 98.1 and 98.5%, respectively. Nonetheless, the weight fraction of the  
49  
50 desired HEB phase was 94 % at most, while amounts of  $\text{HfO}_2$  up to 7.0 wt.% were also found in the  
51  
52 products. In addition, despite the XRD analysis results, the EDS maps clearly show that the  
53  
54 agglomeration of certain species is often present across of the sintered samples [21,22]. Thus, the studies  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1  
2  
3 conducted so far evidenced that the fabrication of pure HEBs in massive form still represents a crucial  
4  
5 issue.

6  
7  
8 In the present work, the reactive SPS (R-SPS) route is first considered for the synthesis and  
9  
10 simultaneous consolidation of  $(\text{Hf}_{0.2}\text{Mo}_{0.2}\text{Zr}_{0.2}\text{Nb}_{0.2}\text{Ti}_{0.2})\text{B}_2$  from elemental reactants. The effect  
11  
12 produced by a change of the heating rates applied during the sintering process is also examined. As an  
13  
14 alternative method, the same reaction promoters were first processed by Self-propagating High-  
15  
16 temperature Synthesis (SHS) technique [32] for the preparation of the HE boride powders to be  
17  
18 subsequently consolidated by SPS, thus considering the so-called SHS-SPS route. It should be noted that  
19  
20 both the R-SPS and the SHS-SPS methods have been successfully employed in the last two decades by  
21  
22 our research group for the fabrication of various standard metal diborides in dense form, such as  $\text{ReB}_2$   
23  
24 [33],  $\text{TaB}_2$  [34,35],  $\text{HfB}_2$  [36,37],  $\text{ZrB}_2$  [35,38] and  $\text{TiB}_2$  [39]. Very recently, preliminarily results  
25  
26 obtained when the SHS-SPS approach was attempted for the preparation of bulk  
27  
28  $(\text{Hf}_{0.2}\text{Mo}_{0.2}\text{Zr}_{0.2}\text{Nb}_{0.2}\text{Ti}_{0.2})\text{B}_2$  were also reported in the literature [20]. In the present paper, the effect  
29  
30 produced by various process parameters (dwell temperature, holding time, heating rate, mechanical load,  
31  
32 etc.) on density, composition and microstructure of products obtained by R-SPS and SHS-SPS are  
33  
34 addressed in detail. The oxidation resistance of the optimal massive HEB material is then compared with  
35  
36 that one of individual diborides prepared following the same processing route and displaying similar  
37  
38 relative density.

## 39 40 41 42 43 44 45 46 47 48 49 **2. Materials and methods**

50  
51 The commercial powders used for R-SPS and SHS experiments are reported in **Table 1** along with  
52  
53 the related characteristics provided by the suppliers. Mixing of reactants was performed according to the  
54  
55 following reactions stoichiometry:  
56  
57

1  
2  
3 The use of an excess of B ( $x > 0$ ) was also considered, based on previous outcomes found when  
4 synthesizing standard transition metal diborides following the same routes [25,35,38]. In addition, the  
5 effect produced by the reduction of Mo particles size was examined.  
6  
7  
8  
9

10 Powder mixing was carried out for 20 min in a SPEX 8000 (SPEX CertiPrep, USA) shaker mill  
11 using plastic vials and alumina balls. The obtained mixture was first cold-pressed to form cylindrical  
12 pellets, to be reacted inside a stainless-steel chamber filled with Argon, using an electrically heated  
13 tungsten filament as ignitor. Details of the SHS set-up and procedure can be found elsewhere [40]. The  
14 synthesis product was crashed in a mortar to convert it in powder form. The obtained powders were  
15 subsequently milled for different time intervals ( $t_{BM} = 5-60$  min) using the milling device above, with  
16 stainless steel vial and two steel balls (13 mm diameter, 8 g weight), being the resulting ball-to-powder  
17 weight ratio equal to 2. Particle size of the resulting powders was determined by laser light scattering  
18 analysis (CILAS 1180, France).  
19  
20  
21  
22  
23  
24

26  
27  
28  
29  
30  
31

32  
33 Reactive sintering experiments and the densification of SHS powders were both performed using  
34 a SPS apparatus (515S model, Fuji Electronic Industrial Co., Ltd., Kanagawa, Japan) under temperature-  
35 controlled mode and vacuum (20 Pa) conditions. About 4.4 g of powders were placed inside a hollow  
36 cylinder (30 mm external diameter; 15 mm inside diameter; 30 mm height) equipped with two punches  
37 (14.7 mm diameter, 20 mm height), all made of AT101 graphite (ATAL Srl., Italy). The temperature  
38 during SPS was measured by a C-type thermocouple (Fuji Electronic Industrial Co., Ltd., Kanagawa,  
39 Japan) inserted inside a small hole drilled on the lateral surface of the graphite die. An infrared  
40 pyrometer (CHINO, mod. IR-AHS2, Japan) focused on the lateral surface of the die was also used. The  
41 imposed thermal cycle consists of increasing the temperature from the room value to the maximum level  
42 ( $T_D$ ) with a prescribed heating rate ( $HR$ ), i.e. 100 or 200°C/min. The  $T_D$  value was then maintained  
43 constant for different dwell time periods ( $t_D$ ) up to 20 min. The effect of  $T_D$  on the density and  
44 composition of the sintered product was investigated in the range 1800–1950 °C. The applied  
45  
46  
47  
48  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1  
2  
3 mechanical pressure was varied in the range 20-70 MPa. For the sake of reproducibility, each  
4  
5 experiment was repeated at least twice.  
6

7  
8 Important information on the dynamics of the SPS process can be provided by the temporal changes  
9  
10 of the recorded sample displacement. However, although the latter one is generally regarded as the  
11  
12 degree of powder compact densification, thermal expansion of the sample, as well as that of both  
13  
14 electrodes, graphite blocks, spacers and plungers, are also responsible for the variation of this parameter.  
15  
16

17  
18 After SPS, the bulk samples were cut, ground and polished using progressively finer abrasive paper  
19  
20 for further characterization. Their relative densities were evaluated by the Archimedes' method using  
21  
22 distilled water as immersing medium and  $8.67 \text{ g/cm}^3$  as theoretical value [4].  
23  
24

25  
26 Phases identification and structural characteristics of the synthesized powders and sintered products  
27  
28 was carried by X-ray diffraction analysis (Philips PW 1830, Netherlands) using  $\text{Cu } K_{\alpha}$  radiation, over a  
29  
30 range of scattering angles  $2\theta$  from 20 to 130, in steps of  $0.05^{\circ}$  with 15 s acquisition time per angle.  
31  
32 Phases content and the corresponding microstructural parameters were evaluated with the Rietveld  
33  
34 method by analyzing the XRD patterns with the MAUD program [41].  
35  
36  
37

38  
39 The obtained SHS powders, R-SPS and SHS-SPS samples were also examined by high resolution  
40  
41 scanning electron microscopy (HRSEM) (mod. S4000, Hitachi, Tokyo, Japan) equipped with a UltraDry  
42  
43 EDS Detector (Thermo Fisher Scientific, Waltham, MA, USA).  
44  
45

46  
47 The oxidation resistance of the  $(\text{Hf}_{0.2}\text{Mo}_{0.2}\text{Ta}_{0.2}\text{Nb}_{0.2}\text{Ti}_{0.2})\text{B}_2$  product was evaluated by  
48  
49 thermogravimetric analysis (NETZSCH, STA 409PC Luxx Simultaneous DTA-TGA Instrument,  
50  
51 Germany) under 0.1 L/min air flow. Non-isothermal (dynamic) measurements, consisting of slowly  
52  
53 heating ( $2 \text{ }^{\circ}\text{C}/\text{min}$ ) the HEB sample from room temperature to  $1450 \text{ }^{\circ}\text{C}$ , as well as isothermal runs at  
54  
55  $1200 \text{ }^{\circ}\text{C}$  for about 4 h, have been carried out. For the sake of comparison, some individual diborides,  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1  
2  
3 namely  $\text{HfB}_2$ ,  $\text{TaB}_2$ , and  $\text{TiB}_2$ , prepared by SPS and characterized by similar relative densities, were also  
4  
5 tested by DTA-TGA.  
6  
7  
8  
9

### 10 **3. Results and discussion**

#### 11 **3.1. Bulk HEBs via Reactive Spark Plasma Sintering**

12  
13 In principle, the most convenient and direct way to produce massive ceramic bodies is to perform  
14  
15 material synthesis and densification in a single processing step. Accordingly, this approach was first  
16  
17 attempted in this work for the preparation of bulk  $(\text{Hf}_{0.2}\text{Mo}_{0.2}\text{Ta}_{0.2}\text{Nb}_{0.2}\text{Ti}_{0.2})\text{B}_2$ . To this, elemental  
18  
19 reactants mixed in stoichiometric ratio ( $x=0$  in Eq. 1) were first processed by R-SPS under the  
20  
21 conditions of  $T_D = 1950^\circ\text{C}$ ,  $t_D = 20$  min,  $P=20$  MPa and  $HR = 100^\circ\text{C}/\text{min}$ . The temperature time profile  
22  
23 imposed during the process is plotted in **Fig.1a** along with the related sample displacement. **Fig.1b**  
24  
25 shows the corresponding gas pressure evolution inside the SPS chamber during the process which  
26  
27 provides important information, as discussed subsequently. Negative values in the displacement data are  
28  
29 obtained at the initial stage of the R-SPS process. This outcome can be readily motivated by the thermal  
30  
31 expansion contribution of the entire system (sample/die/plungers/spacers/electrodes) to the recorded  
32  
33 displacement, which overcomes, during this period, that one (positive) due to powder densification. On  
34  
35 the other hand, the displacement starts to increase after about 12 min from the beginning of the electric  
36  
37 current application, when the temperature is approximately  $1200^\circ\text{C}$ . Afterward, this parameter is  
38  
39 observed to raise in a gradual manner, first with a nearly constant rate and then with a decreasing one,  
40  
41 until the end of the process. The absolute density of the final R-SPS product was  $8.07\pm 0.01$   $\text{g}/\text{cm}^3$ ,  
42  
43 corresponding to a relative density of about 93%.  
44  
45  
46  
47  
48  
49  
50  
51  
52  
53

54 The compositional changes of the powders undergoing R-SPS was monitored by XRD analysis. In  
55  
56 particular, the corresponding patterns of the product obtained for  $t_D = 20$  min is plotted in **Fig. 2** with  
57  
58 that of the starting mixture. The  $(\text{Hf}_{0.2}\text{Mo}_{0.2}\text{Ta}_{0.2}\text{Nb}_{0.2}\text{Ti}_{0.2})\text{B}_2$  content in the sintered material at the end  
59  
60  
61  
62  
63  
64  
65

1  
2  
3 of the process ( $t_D = 20$  min) was about 63.7% (**Table 2**), to indicate that reaction (1) does not go to  
4  
5 completion. As also reported in **Table 2**, the weight percentage of the desired high-entropy boride phase  
6  
7 in the product when  $t_D = 5$  min ( $t=t_1$  in **Fig. 1**) was approximately 54 wt.%, suggesting that the chemical  
8  
9 transformation of initial reactants takes place gradually during the process. As shown in supplementary  
10  
11 **Table S1**, where details of the different phases content as well as the related microstructural parameters  
12  
13 are reported, various metal borides, along with small amount (about 2 wt.%) of  $\text{HfO}_2$ , are also detected  
14  
15 by XRD analysis.  
16  
17

18  
19  
20 The effect produced by an increase of the heating rate from 100 to 200°C/min is then examined. The  
21  
22 SPS output shown in **Fig. 3a-3b** evidences that a different behavior is displayed by the reacting system  
23  
24 with respect to the case when the dwell temperature is approached at a slower rate (**Fig. 1a**). Indeed, a  
25  
26 sharp sample displacement takes place after approximately 3.2 min ( $t^*$ ) during the non-isothermal stage  
27  
28 conducted at 200 °C/min (**Fig. 3a**). This event is observed to occur when the measured temperature was  
29  
30 slightly above 600°C. The inset in **Fig. 3a** also evidenced that a slight local temperature increase, with  
31  
32 respect to the scheduled thermal cycle, is correspondingly recorded. Moreover, after  $t^*$  the  $\delta$  parameter  
33  
34 decreases for a certain period. Furthermore, during such short time interval, the gas pressure inside the  
35  
36 sintering chamber raised rapidly to relatively high levels (**Fig. 3b**), if compared to the case when the R-  
37  
38 SPS process was performed at 100°C/min (**Fig. 1b**) where, albeit some changes of this parameter were  
39  
40 observed in the course of the experiment, its value did not exceed 80 Pa. Based on all these features, it is  
41  
42 apparent that a combustion synthesis-like reaction, accompanied by a local heat release with a  
43  
44 subsequent sample expansion, took place at  $t^*$ . The latter statement is undoubtedly supported by the  
45  
46 corresponding sudden compositional change, as evidenced by XRD analysis, whose results are shown in  
47  
48 **Fig. 4**. In particular, as shown in **Table 2**, the Rietveld analysis indicated that the product  
49  
50 correspondingly obtained for  $x = 0$  is composed of 58.8% of  $(\text{Hf}_{0.2}\text{Mo}_{0.2}\text{Ta}_{0.2}\text{Nb}_{0.2}\text{Ti}_{0.2})\text{B}_2$ , with various  
51  
52 secondary boride phases and  $\text{HfO}_2$  (see supplementary **Table S1**). According to previous studies  
53  
54  
55  
56  
57  
58

61  
62  
63  
64  
65

1  
2  
3 addressed in the literature to the preparation of standard diborides ( $ZrB_2$ ,  $HfB_2$ , etc.) by R-SPS  
4  
5 [35,36,38], where the use of a slight excess of boron (5-10 mol%) is usually beneficial to compensate  
6  
7 the loss of this reactant due of the presence of some oxides and impurities in the raw powders, the x  
8  
9 parameter in Eq. 1 was increased up to 0.2. Consistently, as shown in **Fig. 4**, the latter x value is found  
10  
11 to improve the composition of the R-SPS product, being the yield in the desired HEB in the product at  $t^*$   
12  
13 equal to 64.5%. Very important is the fact that no oxides are detected in the product prepared using such  
14  
15 excess of boron (see supplementary **Table S1**). It is also found that the progress of the R-SPS process up  
16  
17 to  $t_D = 20$  min determined only a slight improvement in product composition, with a  
18  
19  $(Hf_{0.2}Mo_{0.2}Ta_{0.2}Nb_{0.2}Ti_{0.2})B_2$  content equal to 66.7 wt.%.

20  
21  
22  
23  
24 As far as powder densification is concerned, rather low densities (about  $5.7 \text{ g/cm}^3$ ) were reached at  
25  
26 the end of the R-SPS process, if the applied pressure was maintained equal to 20 MPa during the entire  
27  
28 process duration. On the other hand, the initial application of higher mechanical loads is not appropriate,  
29  
30 for safety and other reasons, when strongly exothermic systems prone to react under the combustion  
31  
32 synthesis regime are processed [38]. Following the approach suggested in the literature for similarly-  
33  
34 behaving systems [34,36,42], a two-stage mechanical load cycle, where the mechanical load is  
35  
36 augmented nearly after the occurrence of the combustion synthesis reaction ( $t^*$ ), is therefore considered.  
37  
38 The effect of such change in the applied pressure is investigated in the range 20-70 MPa and the  
39  
40 obtained results are shown in **Fig. 5**. As the mechanical pressure is augmented from 20 to 40 MPa, the  
41  
42 average value of the density rises significantly, up to  $7.6 \text{ g/cm}^3$ , while a further increase to 70 MPa  
43  
44 determines a relatively lower effect. Approximately  $8 \text{ g/cm}^3$  dense samples are correspondingly  
45  
46 accomplished. It should be noted that the variation of the x parameter was found to produce a very  
47  
48 modest effect on sample density.

49  
50  
51 Phases distribution and the microstructure of the sintered materials were also examined by SEM  
52  
53 coupled with EDX analysis. The obtained results agree with the XRD analysis and density  
54  
55

1  
2  
3 measurements. Indeed, as shown in **Fig. 6a**, despite the reasonably good consolidation level reached at  
4  
5 the end of the R-SPS process conducted under low heating rates (100°C/min), the non-uniform  
6  
7 elemental distribution shown by EDS maps provides a clear indication that a single-phase product is  
8  
9 very far from being achieved. Apparently, a slightly improvement in the distribution of Hf, Mo and Ta  
10  
11 elements can be observed across the sample prepared at higher heating rates (200°C/min), albeit zones  
12  
13 with higher local concentrations of Nb and Ti can be clearly seen (cf. **Fig. 6b**). In addition, product  
14  
15 microstructure is characterized by the presence of some large isolated pores 10-15  $\mu\text{m}$  sized (indicated  
16  
17 by the arrow in **Fig. 6b**), along with several smaller ones. Such pores can be likely ascribed to the gases  
18  
19 suddenly liberated during the occurrence of the combustion synthesis event. Indeed, the volatilization of  
20  
21 some impurities initially present in the powders and/or generated during synthesis reactions takes place  
22  
23 inside a nearly closed container, so that the produced gases could hardly escape and remain entrapped  
24  
25 within the bulk product. Another negative aspect worth to be mentioned when considering the  
26  
27 preparation of HEBs by R-SPS is the observed sample weight loss, which was found to reach values  
28  
29 even exceeding 10 wt.%, for the case of synthesis reactions evolving under the combustion regime. Both  
30  
31 these drawbacks above could be readily associated to the gases liberated in a very short time interval,  
32  
33 which determine a marked pressure increase inside the die, as shown in **Fig. 3b**. Consequently, part of  
34  
35 the powders undergoing R-SPS are forced out of the die.  
36  
37  
38  
39  
40  
41  
42  
43

44 Another parameter that could play a beneficial role for promoting reaction completion during the R-  
45  
46 SPS process is represented by particles size of initial reactants. Based on the data provided by the  
47  
48 vendors (Table 1), Ti and Mo powders are relatively coarser with respect to the other ones used in this  
49  
50 work. In addition, while Ti is expected to melt under the adopted R-SPS condition, the use of finer Mo  
51  
52 powder could provide more valuable indication in this regard. Accordingly, additional R-SPS  
53  
54 experiments using  $< 44 \mu\text{m}$  sized Mo powders, obtained after sieving the original commercial ones,  
55  
56 were carried out. The cross-sectional SEM micrograph and the related EDX elemental maps of the  
57  
58  
59  
60  
61  
62  
63  
64  
65

1  
2  
3 corresponding sample produced by R-SPS ( $HR = 100\text{ }^\circ\text{C}/\text{min}$ ,  $T_D = 1950\text{A}$ ,  $t_D = 20\text{ min}$ ,  $P = 20\text{ MPa}$ ) is  
4  
5 reported in supplementary Fig. S1. It is clearly seen that, a slight improvement in term of elemental  
6  
7 distribution is attained with respect to the sample achieved under the same conditions, except for the use  
8  
9 of coarser Mo powders (Fig. 3a). However, the sintered product appears still rather porous and not  
10  
11 homogeneous, so that powder consolidation and, above all, the completeness of the reaction to provide  
12  
13 the desired dense high-entropy single phase material by R-SPS, is far from being reached.

18  
19  
20  
21

### 22 **3.2. Powder preparation by SHS**

23  
24  
25 Once the mixture of reactants combined according to Eq. (1) was locally ignited, a self-sustaining  
26  
27 combustion front was generated. This behavior was typically observed when the same approach was  
28  
29 considered for the synthesis of individual transition metal diborides, like TaB<sub>2</sub> [34], HfB<sub>2</sub> [37], TiB<sub>2</sub>  
30  
31 [39], and ZrB<sub>2</sub> [35], and is readily due to their strong exothermic character, i.e. ( $-\Delta H_f^0$ ) = 209.200,  
32  
33 335.975, 323.800, and 322.586, kJ/mol, respectively [43]. The reaction front associated to Eq. (1) was  
34  
35 found to propagate very fast (about 2 sec in a 20 mm high pellet), with an average velocity of  $4.75\pm 0.25$   
36  
37 mm/s, whereas the measured combustion temperature was  $2150\pm 100\text{ }^\circ\text{C}$ . The transformation of the  
38  
39 initial reactants to the expected HEB phase was verified by analyzing the SHS product by XRD. The  
40  
41 obtained results are shown in **Fig. 7** for different x values and the corresponding percentage of the  
42  
43 detected phases are listed in supplementary **Table S2** along with the corresponding microstructural  
44  
45 parameters. From the yield in  $(\text{Hf}_{0.2}\text{Mo}_{0.2}\text{Ta}_{0.2}\text{Nb}_{0.2}\text{Ti}_{0.2})\text{B}_2$  summarized in **Table 2**, it is seen that a  
46  
47 significant improvement in term of material composition was achieved when operating with an excess of  
48  
49 boron equivalent to  $x=0.2$  in Eq. 1. Indeed, under the latter condition, about 96 wt.% of elemental  
50  
51 reactants are converted to the desired phase, as revealed by the Rietveld analysis. Minor amounts of  
52  
53  
54  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1  
2 other secondary phases, namely  $(\text{Ta}_{0.5}\text{Ti}_{0.5})\text{B}_2$ ,  $(\text{Hf}_{0.5}\text{Ti}_{0.5})\text{B}_2$ ,  $\text{HfB}_2$ , as well as traces of  $\text{HfO}_2$ , are also  
3  
4  
5 detected in the end product.  
6

7 The produced powders were also examined by SEM and EDX analysis. **Fig. 8** evidenced that a good  
8  
9 mixing level between the different elements is reached inside each grain. Nonetheless, some regions  
10  
11 with relatively higher/lower metals content can be seen, to confirm that a single-phase product was not  
12  
13 attained at the end of the SHS process.  
14  
15  
16  
17  
18  
19

### 20 **3.3. Consolidation by Spark Plasma Sintering of SHS powders**

21  
22 Three sets of powders were prepared after ball milling the SHS product for 5, 20 and 60 min,  
23  
24 respectively. The resulting particle size characteristics, as measured by laser scattering analysis, are  
25  
26 reported in **Table 3**. The relatively coarse particles attained after 5 min are markedly refined when the  
27  
28 treatment was prolonged to 20 min. In contrast, only minor changes were observed when the milling  
29  
30 period duration was extended to 1 h.  
31  
32  
33

34 The temporal sample displacement changes plotted in **Fig. 9** for the case of  $t_{BM} = 20$  min along with  
35  
36 the corresponding temperature profile indicate that SHS powders exhibits a gradual consolidation  
37  
38 behavior during SPS ( $T_D = 1950^\circ\text{C}$ ,  $P = 20$  MPa,  $HR = 200^\circ\text{C}/\text{min}$ , and  $t_D = 20$  min). It is seen that only  
39  
40 negligible changes of the  $\delta$  parameter are recorded up to 7 min, when the corresponding measured  
41  
42 temperature was about  $1200^\circ\text{C}$ . The compact is observed to mostly densify during the non-isothermal  
43  
44 stage, while, after the  $T_D$  value is reached, sample consolidation continues at a lower rate until the end of  
45  
46 the process ( $t_D = 20$  min). A similar qualitative behavior was shown by the differently milled powders.  
47  
48  
49  
50

51 The effect of the dwell temperature on the density of SPS specimens resulting from these three  
52  
53 groups of powders can be deduced from **Fig. 10**. As expected, product densification is progressively  
54  
55 enhanced as the sintering temperature was augmented. The effect of milling time is mainly observed at  
56  
57 relatively lower  $T_D$  values, whereas it tends to vanish when operating at  $1950^\circ\text{C}$ , particularly when the  
58  
59  
60  
61  
62  
63  
64  
65

1  
2  
3 milling treatment was prolonged from 20 to 60 min. This outcome is consistent with the similar particles  
4  
5 size of these two groups of powders (**Table 3**). It should be mentioned the fact that all the experiments  
6  
7 described so far were carried out under an applied pressure of 20 MPa. Nonetheless, as reported in  
8  
9 supplementary **Fig. S1-S2**, an increase of the latter parameter up to 45 MPa did not provide valuable  
10  
11 beneficial effects.  
12  
13

14  
15 Apart from the densification issue, the other relevant aspect to consider is represented by the  
16  
17 composition of the sintered material, since the SHS powders to be consolidated did not consist  
18  
19 exclusively of the desired HEB phase. From the XRD analysis of the SPS product obtained 1950°C,  
20  
21 whose results are reported in **Fig. 11** along with those ones corresponding to the starting SHS powders  
22  
23 milled for 20 min, it is seen that the synthesis reaction went to completion during SPS. Indeed, as  
24  
25 summarized in **Table 2** (details can be found in supplementary **Table S2**), a single-phase product is  
26  
27 finally achieved with no evidence of the presence of secondary borides, oxides, etc., species.  
28  
29  
30

31  
32 Important features can be deduced when examining the SEM micrographs and related EDS maps  
33  
34 reported in **Fig. 12** for different holding temperatures and milled powders. First, from **Fig. 12a** it is  
35  
36 apparent that samples sintered at 1850°C are characterized by a marked residual porosity, other than a  
37  
38 non-uniform elements distribution across the sample. While, in accordance with data reported in **Fig. 11**,  
39  
40 an increase of the  $T_D$  value to 1900°C determines a marked improvement in term of product  
41  
42 densification, the homogenization of the high-entropy phase is still not adequate (**Fig. 12b**). The  
43  
44 temperature needs to be further raised to 1950°C for achieving a satisfactory uniformity in composition  
45  
46 across the SPS sample (**Fig. 12c**), in addition to a reduction of residual porosity. Finally, **Fig. 12d**  
47  
48 evidences that the prolonged milling treatment from 20 to 60 min is accompanied by a further  
49  
50 improvement of product microstructure. This is likely due to the reduction of the diffusion distances  
51  
52 between the various phases during the mechanical treatment, so that the distribution of elemental species  
53  
54 within the sample volume is facilitated during SPS and product homogenization enhanced.  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

### 3.4. Oxidation behavior of sintered samples

The oxidation behavior of the optimal HEB samples obtained in this work, i.e. about 92.5% dense and consisting exclusively of  $(\text{Hf}_{0.2}\text{Mo}_{0.2}\text{Ta}_{0.2}\text{Nb}_{0.2}\text{Ti}_{0.2})\text{B}_2$ , was examined by performing dynamic and isothermal TGA experiments in air flow. The corresponding curves, expressed as normalized weight gain, are compared in **Fig. 13a-13b**, respectively, with the results relative to standard individual diborides prepared according the SHS-SPS route and characterized by similar relative densities, namely  $\text{HfB}_2$  (92.8%),  $\text{TaB}_2$  (94.4%), and  $\text{TiB}_2$  (93.1%). The dynamic tests conducted up to 1450°C clearly indicated that the system more sensitive to the oxidizing environment is  $\text{TiB}_2$ , whose curve starts to raise at about 450°C and displayed the larger weight gain, with respect to the other diborides, during the entire temperature interval investigated (**Fig. 13a**). Also  $\text{TaB}_2$  shows, although at a lower level compared to  $\text{TiB}_2$ , scarce resistance to oxidation, since its mass progressively increases for temperature higher than 600°C. In contrast, both  $\text{HfB}_2$  and HEB specimens exhibit only moderate weight changes for temperature lower than 1200-1300°C. On the other hand, the HE ceramic oxidized markedly for temperatures exceeding 1300°C, as proven by the corresponding sudden raise of the related curve.

Based on the latter outcome, the isothermal TGA tests were conducted at 1200°C. In addition, the  $\text{TiB}_2$  sample was not considered for such experiments, due to the behavior manifested by this system during oxidation experiments carried out under dynamic conditions. The corresponding results reported in **Fig. 13b** are fully consistent with those ones obtained from non-isothermal tests. Indeed, while the  $\text{TaB}_2$  sample was subjected to a significant mass gain during the test, both  $\text{HfB}_2$  and the high entropy ceramic exhibited low and thermally stable oxidation rate. In this regard, it should be noted that the latter two specimens are both characterized by relatively lower relative densities with respect to  $\text{TaB}_2$  and  $\text{TiB}_2$ , so that they are, in principle, more exposed to oxygen diffusion.

1  
2  
3 On the basis of the results described above, it is possible to conclude that the oxidation up to 1200°C  
4  
5 of the monophasic UHTC materials taken into account in the present work occurs according to the  
6  
7 following hierarchical order:  $TiB_2 > TaB_2 > HfB_2 > (Hf_{0.2}Mo_{0.2}Ta_{0.2}Nb_{0.2}Ti_{0.2})B_2$ . These finding agrees  
8  
9 with the oxidation test results conducted for the same systems by **Gild et al. [4]** using a tube furnace at  
10  
11 different temperatures under flowing dry air. In particular, the high-temperature oxidation performances  
12  
13 of the high-entropy, hafnium-, tantalum-, and titanium diborides investigated by **Gild et al. [4]** followed  
14  
15 the order obtained, as indicated above, in the present work.  
16  
17  
18  
19  
20  
21

#### 22 **4. Concluding remarks**

23  
24 The identification of efficient processing routes for the fabrication of pure and dense high-entropy  
25  
26 diborides certainly represents a crucial problem for the development of this novel class of ceramics.  
27  
28 However, since the pioneering work by **Gild et al. [4]**, various difficulties were encountered for their  
29  
30 synthesis and consolidation. Accordingly, the same authors recently pointed out that the originally  
31  
32 proposed intense mechanical treatment of the individual diborides constituents before their processing  
33  
34 by SPS is not convenient, to avoid significant product contamination and oxidation [14].  
35  
36  
37  
38

39 In the present work, the one-step synthesis and consolidation by reactive SPS of  
40  
41  $(Hf_{0.2}Mo_{0.2}Ta_{0.2}Nb_{0.2}Ti_{0.2})B_2$  using elemental powders was first investigated. The sintering process was  
42  
43 conducted for 20 min at 1950°C under different heating rate conditions. When the temperature was  
44  
45 increased to the maximum level at 100°C/min, the transformation of reactants occurred through a  
46  
47 gradual solid-state diffusion mechanism. In contrast, if heating rates equal to 200 °C/min are set, the  
48  
49 synthesis reaction evolved under the combustion regime. In both cases, the synthesis reaction did not go  
50  
51 to completion, with a conversion of reactants to the desired high-entropy phase of about 67 wt.%, at  
52  
53 most, although a good densification level was achieved, i.e. 91.3-93% relative density. SEM and EDS  
54  
55 analysis confirmed that the obtainment of a single-phase product is far from being reached. In addition,  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1  
2  
3 isolated large pores were found in the sintered material when combustion synthesis reactions took place  
4  
5 during the R-SPS process.  
6

7  
8 Significant improvement in the high-entropy material characteristics are obtained when the  
9  
10 elemental powders were first reacted in few seconds by SHS and subsequently processed by SPS. As for  
11  
12 the first step, the best result was reached when using 10 mol% excess of boron, with respect to the  
13  
14 stoichiometric value, which allowed us to achieve about 96% conversion of initial reactants to  
15  
16  $(\text{Hf}_{0.2}\text{Mo}_{0.2}\text{Ta}_{0.2}\text{Nb}_{0.2}\text{Ti}_{0.2})\text{B}_2$ . Moreover, when the resulting powders were then processed by SPS for 20  
17  
18 min at 1950°C and 20 MPa, a 92.5% dense single-phase material was produced. The obtainment of a  
19  
20 homogeneous material was clearly proven by accurate XRD analysis coupled with the Rietveld  
21  
22 analytical procedure, SEM observations and EDS. Currently, work is on progress to further increase the  
23  
24 densification level of the sintered product. In this regard, but also with the aim of promoting the  
25  
26 completeness of the synthesis reaction during SHS and R-SPS processes, the use of finer reactants  
27  
28 powder will be considered in further investigations. Nonetheless, the fact that no trace of secondary  
29  
30 phases was found in the bulk material produced in this work represents a very important achievement, if  
31  
32 compared with the results reported so far in the literature for the HEB taken into account. For instance,  
33  
34 the oxides contamination was reported in the 92.2% dense  $(\text{Hf}_{0.2}\text{Mo}_{0.2}\text{Ta}_{0.2}\text{Nb}_{0.2}\text{Ti}_{0.2})\text{B}_2$  material  
35  
36 obtained by **Gild et al. [4]**. In addition, despite of the higher density level (98.5%) recently reached by  
37  
38 **Zhang et al. [22]** for the same system, the yield in the high-entropy phase was 93 wt.% only, with about  
39  
40 7 wt.% hafnium oxides. The latter impurity was also detected by XRD analysis in the 95% dense  
41  
42 material prepared by the same authors, using B, instead of  $\text{B}_4\text{C}$  and C, as precursors for the boro-thermal  
43  
44 reduction of metal oxides [21]. Furthermore, EDX compositional maps evidenced that some species,  
45  
46 mainly Nb, are not homogeneously distributed across the sample volume.  
47  
48  
49  
50  
51  
52  
53  
54  
55

56  
57 The results deriving from dynamic and isothermal oxidation tests carried out on the  
58  
59  $(\text{Hf}_{0.2}\text{Mo}_{0.2}\text{Ta}_{0.2}\text{Nb}_{0.2}\text{Ti}_{0.2})\text{B}_2$  material obtained by SHS-SPS are rather promising, if compared to those  
60  
61  
62  
63  
64  
65

1  
2  
3 ones relative to individual Ta-, Ti-, and Hf diborides produced with the same processing method and  
4  
5 displaying slightly higher relative densities. In this regard, it is well recognized that metal borides are  
6  
7 not able to withstand oxidative environments at high temperature, unless appropriate, generally Si-  
8  
9 containing, additives are introduced in the matrix. Nonetheless, the high-entropy ceramic was shown to  
10  
11 exhibit, similarly to HfB<sub>2</sub>, very low and stable oxidation rate up to 1200°C, whereas TiB<sub>2</sub> and TaB<sub>2</sub> gain  
12  
13 markedly their weight at lower temperatures, i.e. about 450 and 650°C, respectively. This outcome is  
14  
15 very promising in view of the possible utilization of this ceramic for high temperature applications in  
16  
17 aggressive conditions. Further improvements on this property are certainly expected, if samples with  
18  
19 higher relative densities are made available.  
20  
21  
22  
23  
24  
25

## 26 **Acknowledgements**

27  
28 The present work has been carried out in the framework of the ARCHIMEDES project sponsored by  
29  
30 Regione Autonoma della Sardegna (Italy) - Fondo di Sviluppo e Coesione (FSC) 2014-2020 (Cod. RAS:  
31  
32 RASSR88309, Cod. CUP: F76C18000980002). One of the authors (G.T.) performed her activity in the  
33  
34 framework of the International PhD in Innovation Sciences and Technologies at the University of  
35  
36 Cagliari, Italy. One of us (G.C.) acknowledges the results obtained in this manuscript as quite important  
37  
38 for the “Ithermal” and “Generazione E” projects, sponsored by Sardegna Ricerche, Italy (Cod. CUP:  
39

**Table 1.** Characteristics of powder reactants used for reactive SPS and SHS experiments

<b>Reactant</b>	<b>Vendor, code</b>	<b>Particle size (<math>\mu\text{m}</math>)</b>	<b>Purity (%)</b>
Hf	Alfa Aesar, cod. 10201	< 44	99.6
Mo	Aldrich, cod 26.689-2	< 149	$\geq 99$
Ta	Alfa Aesar, cod 00337	< 44	99.9
Nb	Alfa Aesar, cod 010275	< 44	99.8
Ti	Aldrich, cod 26.849-6	< 149	99.7
B, amorphous	Aldrich, cod 15580	-	$\geq 99$

**Table 2.** HEB yields and related experimental conditions adopted in this work for the fabrication of  $(\text{Hf}_{0.2}\text{Mo}_{0.2}\text{Ta}_{0.2}\text{Nb}_{0.2}\text{Ti}_{0.2})\text{B}_2$ . Details of the secondary phases content and microstructural parameters are reported in supplementary **Table S1 and S2**.

Method	Sample type	B/Me ratio ( $x$ )	SPS conditions ( $HR, T_D, t^*/t_D, P$ )	Yield in HEB (wt.%)
R-SPS	Bulk	0	100°C/min, 1950°C, $t_D = 5$ min, 20 MPa	54.1
R-SPS	Bulk	0	100°C/min, 1950°C, $t_D = 20$ min, 20 MPa	63.7
R-SPS	Powder	0	200°C/min, 1950°C, $t^*$ , 20 MPa	58.8
R-SPS	Powder	0.2	200°C/min, 1950°C, $t^*$ , 20 MPa	64.5
R-SPS	Bulk	0.2	200°C/min, 1950°C, $t_D = 20$ min, 20-70 MPa	66.6
SHS	Powder	0	-	36.7
SHS	Powder	0.1	-	47.1
SHS	Powder	0.2	-	96.2
SHS-SPS	Bulk	0.2	200°C/min, 1950°C, $t_D = 20$ min, 20 MPa	100
