To the reader,

this volume contains the long papers of the Sinergie-SIMA 2024 Management Conference, hosted by the University of Parma on June 13th and 14th 2024.

Theory and practice in the field of management have been challenged by the emergence of sustainability and well-being as major global policy priorities. Both sustainability and well-being are complex, value-laden, and strongly interconnected; however, they tend to exist in separate realms.

Sustainability literature has recorded an evolution in the way the concept of sustainable development is understood, leading to the articulation of sustainable development as human “well-being” and “flourishing”, rather than “needs”. Nevertheless, some scholars have pointed out a lack of clarity in the conceptualization, which causes some ambiguity in terms of definition (Ronen & Kerret, 2020). Kjell (2011) observed that human needs and well-being are poorly understood, characterized, and developed by sustainability research. Along the same vein, Helne & Hirvilammi (2015) observed that the overarching goal of sustainable development (i.e., well-being) has often been narrowly interpreted, mainly in economic terms, while connections between the natural environment and human flourishing have been overlooked. More recently, O’Mahony (2022) remarked that the literature conceptualizing human well-being continues to exist largely outside sustainable development. Hence, placing well-being more clearly within the sustainability framework could be highly beneficial to sustainability.

Concurrently, the literature on well-being is almost entirely dissociated from the contributions of nature or the relationships with ecological and planetary systems (Roberts et al., 2015), and the importance of social dimensions is an emergent conclusion. Therefore, the rationale of contextual systems inherent to sustainability research (incorporating views of times, society, and biosphere) could significantly enrich well-being research, fostering a more holistic perspective on well-being and an increased awareness of the limits of individual well-being pursuits (Kjell, 2011).

In brief, though well-being has major implications for sustainable development and vice versa, the body of literature that effectively integrates sustainability and well-being remains in an embryonic stage.

The above considerations aim to act as catalysts for an interdisciplinary debate within the field of management. Enriching the conception of flourishing well-being in sustainability and the contribution of nature to well-being can produce impactful scientific research, as O’Mahony (2022) points out. Equally important is the analysis of the links between sustainability and well-being, encompassing synergies and trade-offs at the organizational level, in value chains, and in interactions with stakeholders across various industries.

The Sinergie-SIMA 2024 Management Conference welcomed contributions based on different theories, methodological approaches, and units of analysis with the potential to empower a transformation for flourishing individuals, society, and the natural world alike. More precisely, the Conference was a great occasion to discuss the research efforts of our research community within tracks related to the:

- Conference theme (Management of sustainability and well-being for individuals and society),
- SIMA thematic groups (Entrepreneurship, Innovation & Technology Management, Intelligenza manageriale nel management, International Business, Marketing, Purpose-driven Businesses, Retailing & Service Management, Small & Family Business, Strategic Communication, Strategy & Governance, Supply Chain Management, Logistics & Operations, Sustainability, and Tourism & Culture Management),
- special tracks (Examining the social and environmental relevance of sustainable digital business models: Impact on business practices and consumers, Growing resilient Italian SMEs, and Perspectives on grand challenges in international business and implications for companies),
- Management Case Studies.

The Conference call for papers gave the opportunity to submit either short and long papers. Overall, the editorial staff received 277 submissions of which 215 short papers and 62 long papers.

For the *short and long papers*, the evaluation followed the peer review process, with a double-blind review performed by, respectively, one or two referees - university lecturers and experts about the topic - selected among SIMA and the community of Sinergie members.

In detail, the referees applied the following criteria to evaluate the submissions:

- clarity of the research aims,
- accuracy of the methodological approach,
- contribution in terms of originality/innovativeness,
- theoretical and practical contribution,
- clarity of communication,
- significance of the bibliographical basis.

The *peer review* process resulted in full acceptance or rejection of the submissions. In the case of disagreement among reviewers' evaluations, the decision was taken by the Chairs of the SIMA thematic groups or conference track. Each work was then sent back to the Authors together with the referees' reports. The suggestions received by the referees were used by the Authors during the presentation of their research works at the Conference.

The evaluation process ended with the acceptance of 211 short papers and 58 long papers. This volume proposes the papers whose Authors have authorized their publication.

All the long papers published in this volume were presented and discussed during the Conference and published online on the web portal of Sinergie-SIMA Management Conference (<https://www.sijmsima.it/>).

While thanking all the Authors, Chairs, and participants, we hope that this volume will contribute to advance knowledge about the management of sustainability and well-being for individuals and society.

The Conference Chairs

Guido Cristini, Beatrice Luceri, Arabella Mocciaro Li Destri, and Marta Ugolini

SUMMARY

Track 1 - Entrepreneurship

<i>Empowering Student Innovators: Framing Entrepreneurship Education in Europe</i> CHIARA BARTOLI, FEDERICA BRUNETTA, CHRISTIAN LECHNER	PAG.	3
<i>Entrepreneurial Education as a transition driver from informal to formal entrepreneurship in complexity context: the AWE program.</i> FABIO GRECO, FRANCESCO CARIGNANI, FRANCESCO BIFULCO	“	11
<i>Fostering Entrepreneurial Thinking: Analysing the Drivers and Impact of Entrepreneurship Education</i> DARIO PEIRONE, JUDY YUEH LING SONG	“	17
<i>Students' entrepreneurial intentions among personal and contextual factors: a pilot study exploring the role of emotions.</i> ROSSELLA BARATTA, PIERMATTEO ARDOLINO, DIEGO BELLINI, SERENA CUBICO, FRANCESCA SIMEONI	“	23
<i>Social Entrepreneurship and Sustainability. How can challenge-based learning impact students' entrepreneurial skills and challenge providers' problems?</i> ALESSANDRA SCROCCARO	“	31
<i>Humane entrepreneurship and the circular economy: an empirical investigation.</i> MASSIMILIANO VESCI, ROBERTA DE ANGELIS	“	33
<i>Is Passion a Driver of Sustainable Entrepreneurship? An Autobiographic Analysis of Fashion Entrepreneurs</i> CECILIA PASQUINELLI, SERENA ROVAI, MATILDE MILANESI, SIMONE GUERCINI	“	39
<i>Social Innovation: a literature review mapping intellectual structure of the field.</i> LORENA GONZALEZ, ELENA CASPRINI	“	45
<i>Inter-organizational knowledge transfer in Open Innovation Ecosystems: the case of Eni's territorial initiative</i> GIORGIO DI FIORE	“	51
<i>Empowering Digital Entrepreneurship: Regulatory Governance in Platform Ecosystems</i> MUHANAD HASAN AGHA, VLADIMIR KOROVKIN, SVETLANA MIRONYUK	“	57
<i>The Governance of Entrepreneurial Ecosystems: Ecosystem Manager or Ecosystem Act?</i> GABRIELE IANIRO, MICHELE MODINA	“	59
<i>A comprehensive exploration of the knowns and unknowns of Private Equity Secondary Markets</i> MICHELE LERTORA, CRISTINA DE SILVA, MARGHERITA MIETTO, ANNA GERVASONI	“	63
<i>Unveiling The Pitfalls Of Entrepreneurial Team Diversity: Insight From A Post-Mortem Analysis of Failed Start-Ups</i> ADELE PARMENTOLA, MICHELE COSTAGLIOLA DI FIORE	“	69
<i>Agility to Handle Dynamics of Business Transformation</i> GIUSEPPE PIRRONE, MARGHERITA MILOTTA, BIRGIT HAGEN, MARTIN CLOUTIER	“	75
<i>Venture-Builders' Program Design and the creation of Scaleups</i> PAOLA BELINGHERI, CHRISTIAN LECHNER	“	83
<i>Entrepreneurial Ecosystems: exploring the Italian Tech Scaleups scenario</i> SERENA VALENTE, ALESSIA PISONI	“	89
<i>Innovazione e imprenditorialità femminile nelle PMI: un'analisi fuzzy dei driver della performance</i> LUDOVICA ANTENOZIO, DANIELA DI BERARDINO	“	97

Track 2 - Innovation & Technology Management

<i>Beyond Words: Leveraging Language for Strategic Decision-Making in Innovation.</i> MARIA RUCSANDRA STAN, FRANCESCA DI PIETRO, FRANCESCA CAPO	PAG.	105
<i>Combining innovation and business networks for resource mobilization in the meat sector: a case study</i> ALESSANDRO PAGANO, ELISA CARLONI	“	111
<i>The role of purpose in digital companies: a study on Exponential Organizations</i> FRANCESCO DERCHI, NICOLETTA BURATTI, FRANCESCO VITELLARO	“	115
<i>Data Value Chain and Data Ecosystem through digital and traditional tools</i> LORIS SANTARELLI, FEDERICA CECI, MARIANNA SGAMMOTTA	“	123
<i>Web 3.0: il punto di vista dei manager sulle opportunità e le sfide del Metaverso e degli NFT</i> CHIARA BARTOLI, FRANCESCO FASANO, FRANCESCO CAPPÀ, PAOLO BOCCARDELLI	“	129

Track 1 - Entrepreneurship

Empowering Student Innovators: Framing Entrepreneurship Education in Europe

CHIARA BARTOLI¹ FEDERICA BRUNETTA² CHRISTIAN LECHNER³

Abstract. *The work aims to investigate the drivers of student entrepreneurship in the EU by taking the lens of academic programs, in order to frame the contents that should be thought and the environment that should be created to foster student entrepreneurship. Through a systematic literature review and the use of a software-assisted approach, the work allows for the construction of a framework of EU student entrepreneurship that takes into account the key components of the curricula and the education environmental factors that are relevant for the enhancement of entrepreneurial ideas among students. The work emphasizes the importance of the connection between curricula and the entrepreneurial world, the development of soft skills combined with technical competences and interpersonal skills. It also stresses the relevance of providing programs with technological and physical infrastructures and of ensuring continuous teacher training.*

Keywords: *entrepreneurship education, student entrepreneur, European Union, skills*

Background and objectives. *Student entrepreneurs is a valuable lever of economic development and have a strong potential to be a driver of entrepreneurship in Europe. The EU entrepreneurial ecosystem is increasingly dominated by a cohort of young individuals who are introducing digital-first strategies in various sectors, showing in their business project not only technological skills but also a strong focus on making a positive impact within society, prioritizing purpose and passion in their endeavors.*

These include student entrepreneurs, who are a distinctive group with a unique approach to acquiring and using resources compared to entrepreneurs who start businesses outside the university context (Politis et al., 2012). In fact, during their studies, they have a chance to develop entrepreneurial mindset through entrepreneurship education, and to acquire greater flexibility in choosing their career path (Passavanti et.al, 2023). While the magnitude of new ventures created by students or recent graduates is much higher than for professors and researchers, their performances are comparable (Astebro et al. 2012).

Entrepreneurial motivation is the driving force that prompts an individual to translate the intention to start a business venture into concrete actions. These are fueled by either external factors, such as family, friends, and important individuals who offer support, or by internal drive that are passion, personal challenge and the need to realize their dreams, make a difference, and create something significant (Le and Tran, 2021).

In that context entrepreneurship education finds its relevance. Entrepreneurship education is defined as “the process of equipping individuals with the concepts, skills, and abilities necessary for entrepreneurship to recognize opportunities that others have overlooked and to have the self-confidence to act where others have hesitated” (Zhang et al., 2014). Entrepreneurship education can have a positive impact on students' intrinsic motivation, encouraging them to turn their entrepreneurial intentions into concrete actions. Hence, motivated and well-prepared students who have undergone entrepreneurship training programs are more likely to initiate new ventures. Additionally, the key to entrepreneurial success lies not only in the idea itself but also in the passion, determination, and competence to implement entrepreneurial projects.

In Europe, entrepreneurship education is seen as a key factor for lifelong learning (Peric & Peterka, 2020) and to counteract youth unemployment⁴. In coherence with this, in 2016 the Commission launched the European entrepreneurship competence framework (EntreComp), with the aim to foster actions to improve the entrepreneurial ability across the European Union. After the breakout of the COVID Pandemic, there has been a global trend towards promoting entrepreneurship education to equip graduates with the skills and mindset needed to start their own businesses,

European Commission. (2014). Thematic Working Group on Entrepreneurship Education. Available at: https://ec.europa.eu/assets/eac/education/experts-groups/2011-2013/key/entrepreneurship-report-2014_en.pdf

as youth entrepreneurship has been recognized as an antidote to counteract graduate unemployment, especially in the EU.

Entrepreneurship education allows not only student to start their own business, but more importantly it trains their entrepreneurial mindset (Rippa et al., 2023) and increase their flexibility in their career choice (Passavanti et al., 2023). Hence, by means of entrepreneurship education students are equipped with the skills needed to face the job market though a flexible approach, that help them identify opportunities and take risks, work in teams and to be better equipped to solve problems⁵.

The educational context can significantly contribute to the development of essential knowledge and skills that young entrepreneurs need to succeed in their business ventures. Universities, in particular, offer a valuable opportunity to acquire specific knowledge that is crucial for entrepreneurial success (Leiva et al., 2023). In fact, they provide an environment apt to transfer to individuals with specific, valuable knowledge that can leverage entrepreneurship projects and can positively influence the project and ideas of students involved in nascent entrepreneurship in Europe (Leiva et al., 2023). Moreover, co-curricular events can provide a platform for young entrepreneurs to build relationships with successful entrepreneurs, investors, mentors, and other key players in the entrepreneurial ecosystem, thereby facilitating the development of valuable social capital (Honig and Davidsson, 2000).

Hence, though entrepreneurship education, European Universities can contribute to accelerating the transfer of research and development (R&D) knowledge and innovation to the broader business community, thereby stimulating economic growth (Sá and Pinho, 2019). The effectiveness of Entrepreneurial Education (EE) is the object of a debate at European and International level international, covering the multitude of factors that have to be taken into consideration for the entrepreneurship programs to be effective, but also about what activities should be included in programs and what are the most efficient teaching models.

Regarding the factors affecting student intentions to become entrepreneurs, the academic literature agrees that there are multiple determinants that must be taken into account and that intervene in student's willingness to become an entrepreneur, beyond motivations. According to a recent literature review carried out by Maheshwari et al. 2022, six factors should be taken into consideration within the evaluation of University students' willingness to become entrepreneurs that include cognitive factors that are related to attitude toward entrepreneurship, social norms, and perceived behavioral control; personality factors: individuals with a higher risk propensity felt more capable and confident in their entrepreneurial endeavors, positively impacting their intentions to engage in entrepreneurship and environmental factors. Moreover, regional context, formal and informal country-level structures, entrepreneurial purpose, and capital availability, all can also function as a bridge between personal characteristics and entrepreneurial aspirations. In particular, access to funding is crucial for initiating new businesses. However, equally significant are factors like foresight regarding future business sectors and the strength of one's social networks. Also, family support and exposure to entrepreneurial role models, were identified as crucial determinants of students' intentions. Social factors, including prior entrepreneurial experience, had varying impacts on intentions. It is also stated that, educational factors, especially entrepreneurship education, significantly influence students' attitudes and intentions towards entrepreneurship (Maheshwari et al., 2022). A meta-study show that entrepreneurial education increases entrepreneurial intent: this effect is significant and applies also to students that have not shown prior interest in entrepreneurship (Martinez-Gregorio et al., 2021).

Despite the acknowledged role of student entrepreneurship in Europe for the competitiveness of the European single market, and the existence studies analyzing the factors that drive students and individuals to become entrepreneurs are missing there is a lack of works that focus on the content of entrepreneurial education programs, to understand how they should be designed and led in order to be able to act as drivers of student entrepreneurship.

In coherence with these premises, the present work aims to identify the drivers of student entrepreneurship by taking the lens of programs at University level, in order to frame the skills that should thought to foster student entrepreneurship, and to identify the education environmental factors that could be key drivers for the enhancement of student entrepreneurship.

Methodology. In coherence with the aim of deepening the field of knowledge about student entrepreneurship from the point of view of education and training, a Systematic Literature Review has been carried out. Systematic Literature Review (SLR) is considered one of the most effective methods for comprehensively recognizing and analyzing a body of literature pertaining to a specific subject. It serves to showcase existing knowledge while also identifying areas for further research, thereby justifying ongoing contributions to current understanding. (Levy and J. Ellis, 2017). In coherence with Tranfield et al. (2003) prescriptions about the SLR, the reviewing process has been divided into the following four phases (Tranfield et al., 2003): Planning, Execution, Evaluation and Analysis.

⁵ European Commission. (2014). Thematic Working Group on Entrepreneurship Education. Available at: https://ec.europa.eu/assets/eac/education/experts-groups/2011-2013/key/entrepreneurship-report-2014_en.pdf

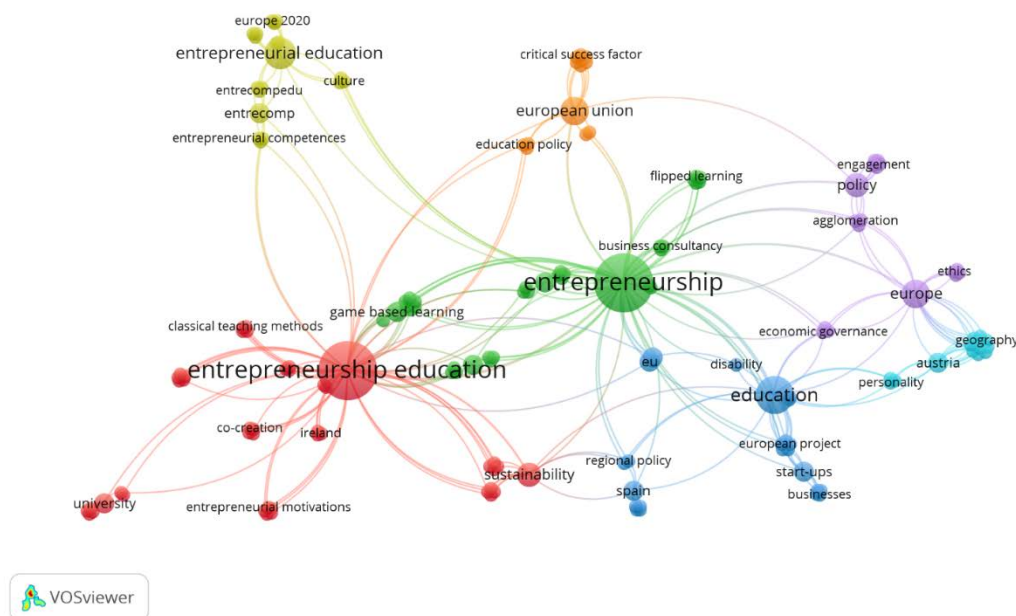

1. *Planning* - A preliminary study about the subject under analysis was carried out in order to deepen the topic and select the keyword for extraction phase, drawing on the grey literature on the subject and restricting the focus to the European Union area.
2. *Execution* - Record extraction was made through the following set of concatenated keywords using Boolean modifiers (Brereton et al., 2007): “entrepreneur*” AND “education” OR “university” AND “European Union” OR “EU”. Extraction was made on SCOPUS database. Extraction was applied to title, abstract and keywords. Data extraction was limited to peer-reviewed scholarly journals written in English, published without any year limit and any limit of discipline, in order to widen the scope of the research. The extraction was made in September 2023. A total number of 188 records were retrieved, duplicates were automatically eliminated. Records were saved for further analysis. Abstracts and article keywords, and main corpus of the article were read. Records not related to the research subject were excluded. The screening resulted in 65 articles selected, saved on .cvs format for further software assisted analysis.
3. *Evaluation* - 39 of the 65 articles were deemed explanatory to the topic under analysis. These were complemented by 3 additional resources identified through snowballing, leading to select 42 resources belonging to 34 scientific journals for further qualitative and quantitative analysis.
4. *Analysis*. To discern the themes covered in the articles, a software-assisted coding process was employed, adhering to the Gioia (2012) methodology. This process unfolded across three phases: an initial phase of open coding, proceeded by axial coding where codes were scrutinized for their interpretative value and organized into pertinent dimensions of significance according to the driving factors, the skills and the challenges, in order to constructing an explanatory framework illustrating core curricula for entrepreneurship education. All the 65 resources were also subjected to bibliometric analysis to visualize co-occurrence networks of important terms from the keywords of the resources extracted in order to frame explaining clusters.

Results

Co-occurrence analysis

The co-occurrence analysis of the resources, which was conducted with VosViewer software on the basis of resource keywords. This allowed for 7 clusters to be identified (minimum cluster size of 12 keyword). Figure 1 visualize the network among the resources. Circles represent the number of co-occurrence while colors identify the clusters.

Fig. 1. Visualization of links among resources and main keywords

Cluster 1 (N= 43 items) contains keywords recalling the content of the programs ; Cluster 2 (N=34 items) suggest the role of technology and sustainability in the programs; Cluster 3 (N=23 items) recalls the role of partnerships with the business world; Cluster 4 (N=19 items) contains keyword that recall the regulatory framework at the EU level; Cluster 5 (N=17 items) comprises keyword that focus on the economic and contextual factors; Cluster 6 (N=14 items), recalls the core competences, finally Cluster 7 (N=13 items) suggests the critical success factors of entrepreneurship education.

Quantitative analysis. The quantitative analysis of the resources shows that the topic began to be of interest to the academy from 2005, the year in which the first contributions were published in peer reviewed scientific journals, and reached its peak in 2021, which corresponds with the year following the COVID-19 pandemic. Of relevance in terms of the number of publications is 2016, which is the year preceding the elaboration of the DIGI COMP, and 2012, to which 6 resources belong and which is the year following the debt crisis in Europe.

Fig. 2. Number of articles published per year

From the point of view of the methodological approach, it emerges that the majority of studies analyzed adopt a field approach to the topic. Quantitative approach characterizes more than 1/5 of the works analyzed, where the survey technique is prevailing. The studies that follow a qualitative approach account for 29% of the total resources, while the number of contributions in the form of reviews (5%) or mixed and method (2%) is limited.

Fig. 3. Methodological approach employed to investigate student entrepreneurship

From the point of view of the countries surveyed, most of the works (17) take into consideration the entire European area, 4 are the works that take into consideration more than one country. There is also considerable interest in the countries of Eastern Europe, and Southern Europe, with particular regard to Spain (4), Italy (3), Greece (3) and Portugal (3).

Fig. 4. Country focus of studies about student entrepreneurship

Qualitative Analysis

Skills to be taught in entrepreneurship programs

Concerning the skills to be thought of, from the coding of the results and discussions of the articles, it is 28 skills that should be taught within entrepreneurship education programmes emerges. These belong to four fundamental categories: cognitive, interpersonal, self-leadership and technical. Table 1 shows the categories and skills identified. Results emphasize that entrepreneurship education is going toward developing enterprising mindsets and reflexive action skills, rather than solely focusing on business building competencies. In fact it is stressed the central role of experiential knowledge within the entrepreneurial learning process, that necessarily has to be completed with traditional Industry-specific knowledge, such as knowledge of technologies, processes or product, management knowledge (business organization, either in administration or management) in order to allow students to acquire specific skills to conduct projects or to establish ventures (Soriano and Castrogiovanni, 2012).

Moreover, it emerges the relevance of adopting a distributed approach to the foundation knowledge and skills needed in entrepreneurship in order to make courses available all students apart from the academic major (Staniewski and Szopiński, 2015). The entrepreneurial approach (López-Núñez et al., 2021) means also developing social and networking competences and the management of teams, together with cognitive skills which relate to the ability to solve complex problems, along with critical thinking, creativity and idea generation (Leiva et al., 2023).

The literature shows that the academy is witnessing a paradigm shift in entrepreneurship education, from theoretical learning “about” to experiential learning (learning ‘for’), the “learning for” is intended to be the acquisition of knowledge that can be used in different contexts and that structure a precise entrepreneurial mindset, including the development of creativity, critical and analytical thinking (Wahid et al., 2017). This also means that teaching models are not suitable for every context and they should be adapted to the specific cultural context where entrepreneurship education occurs (Mets et al., 2021).

Tab. 1. Skills to be thought in academic literature

Skills	Dimension
Ability to generate innovation	Cognitive
Problem solving	
Analytical and critical thinking

Industry specific knowledge	
Research and inquiry skills.	

Facilitators affecting the Program performance

The resource analysis identified 34 main facilitators of student entrepreneurship at the European level and categorized them into 8 key areas.

The literature on student entrepreneurship dwells on the factors that are identified as facilitators of nascent entrepreneurship from student education. These cover multiple areas, which are “business community interaction”, “experiential learning”, “incentives”, “tangible and intangible infrastructure”, “mobility”, “peer to peer interaction”, “self-reflection, and “support and motivation”.

What emerges is that Universities are called upon to project entrepreneurship education through activities that are aimed at creating communities of practices and foster greater student contact with the business world (Jones, 2022). This involves contamination between business and academia, by enhancing active involvement of students in business projects

to create an effective entrepreneurial learning experience for the participants (Karanassios et al., 2006). In addition, studies stress the relevance of entrepreneurial mentoring (Hadjichristodoulou et al., 2020) together role models that are key to enhance the motivation of students. In particular, mentoring appears to be critical for student entrepreneurs (Ahsan et al., 2018).

Another key area concerns the structure of the courses, which should promote experiential learning, through multiple activities such as roleplaying, business simulations (Lesinskis et al., 2021; Perić et al., 2020) and other extracurricular activities (Coleman et al., 2010). Student mobility is also key to develop entrepreneurial mindset, by means of foreign trips and exchange.

Studies also stress relevance of providing students with incentives by means of awards and hackaton that drive the development of ideas and startup projects (Slišāne et al., 2021). Studies also recall added aspects that concern University infrastructures, which include the availability of spaces and systems that allow for the full implementation of experiential learning modes, such as digital systems for e-learning, product modeling tools, and laboratories, along with professional development mechanisms for instructors (Perić et al., 2020).

Tab. 2. Facilitators of entrepreneurship education in academic literature

Facilitator	Area
Networking events Communities of Practice Cooperation Business Secor Workshops Networking events Involvement of Universities in Business Communities	Business community Interaction
Extracurricular activities community work Simulations Guest lecturers Project Learning by doing	Experiential learning
Work with rewards Role model Lectures Awards and Hackatons	Incentives
Entrepreneurial structures in Universities Introduce entrepreneurship education at early stage Education of teacher Continuing education Education of instructors E-learning platforms Integrating digital tools	Tangible and intangible Infrastructures
Student Mobility	Mobility
Interactive Group Work Exchange knowledge Networking events peer-to-peer learning and feedback	Peer to peer Interaction
Individual assignment Role playing More inquiry-oriented approaches	Self -reflection
Business Mentorship Role models Giving feedback Practice	Support & Motivation

Main Challenges for student entrepreneurship

The analysis also reveals challenges that are linked to an effective management of student entrepreneurship in Europe carries out multiple challenges. These can be grouped into the following categories: 1) collaboration; 2) training of educators and 3) entrepreneurial culture.

Studies point out that in order to create a conducive environment for entrepreneurship education in Europe, priority should be given to closing the gap between industry and academia to create a better collaboration between the two worlds (Giancarlo and Squazzoni, 2007).

The need to strengthen entrepreneurial skills and to create an entrepreneurial mindset among students raises the challenge of continuous training of educators, for a constant update of their skills (Amiel et al., 2021). Another major challenge covers entrepreneurial culture. There is a need to foster acceptance of the concept of entrepreneurship at the societal level, and to overcome a perceived lack of added value of entrepreneurship in some cultural contexts (Seikkula-Leino et al., 2021). This means overcoming the barriers of negative attitudes toward becoming entrepreneur (Bilić et al., 2021) through ad hoc and international policies to introduce entrepreneurship education into the national curricula at all levels of education and to promote the use of programs based on "learning by doing" (Karanassios et al., 2010) and to cultivate an entrepreneurial mindset among young Europeans (Fonseca et al., 2012).

Conclusions

The main objective of this study is to unveil the factors that determine the success of entrepreneurship programs in terms of skills to be thought and the enhancer of entrepreneurial ideas among students. The work made it possible to highlight the main drivers and challenges in education programs at University level that govern the creation of student entrepreneurs and to frame a “skill canvas” and thus bridging a research gap. Facilitators of student entrepreneurship are mainly related to the creation of synergies between physical and technological infrastructures, the development of soft skills, the interaction with the entrepreneurial world and with peers, as well as with the development of personal abilities. The work also seems to suggest that key to student entrepreneurship is a balance between theoretical knowledge and practical activities, and this new perspective stems from the mingling of two existing pedagogical approaches. Furthermore, the work frames the contents of the course curricula that should be taken into consideration when planning an entrepreneurship program in order to equip it with the ability to train future entrepreneurs. This should include a mix of factors that concern the strengthening of both technical skills and personal, cognitive and relational competencies.

Entrepreneurial Education as a transition driver from informal to formal entrepreneurship in complexity context: the AWE program

FABIO GRECO¹ FRANCESCO CARIGNANI² FRANCESCO BIFULCO³

Abstract

This working progress research investigates the role of entrepreneurial education in fostering the formalization of informal female entrepreneurship. The modalities of this type of transition are analyzed through a focus on the Academy for Women Entrepreneurs program (AWE). Addressing the complexity of women's informal business practices, especially in socio-economically challenging contexts, the research utilizes qualitative method to explore the transformative impact of the AWE program. Preliminary findings suggest that the AWE's comprehensive approach, emphasizing education, mentorship, and networking, may alleviate multifaceted barriers faced by women entrepreneurs. The paper offers implications into the dynamics of transitioning from informal to formal business, and how entrepreneurship education can be a catalyst for women businesses empowerment.

Key words: *Informal Entrepreneurship; Women Entrepreneurship; Entrepreneurship; Complexity*

Framing of the research. *Informal entrepreneurship refers to the globally widespread economic activities, especially prevalent in underdeveloped and developing countries, operating outside official channels. While these activities are legal in every other aspect, they are not formally recognized by institutions, and their growing importance in complex contexts necessitates targeted strategies for understanding and managing them (Williams, 2014). Moreover, informal entrepreneurship also manifests in more developed geographical areas, taking the form of emerging entrepreneurial realities. Although these comply with the reference that frameworks, they often rely on precarious and provisional structures in the initial phases, which do not provide a solid foundation for sustainable growth and development of new entrepreneurial initiatives. Within the realm of female entrepreneurship, this phenomenon is particularly widespread, especially in complex and less developed socio-economic contexts (Welter et al., 2015; Rashid and Ratten, 2020). Female entrepreneurship represents a vital and multifaceted area of the global economy (Muhammad et al., 2020; Greco et al., 2023), with a presence in various sectors. Its analysis requires a critical examination of the socio-economic and cultural factors influencing its development, including market entry barriers, educational and professional restrictions, gender and ethnic discrimination, and other forms of complexity.*

Entrepreneurial Education.

Education is a fundamental characteristic of entrepreneurial development (Honig and Martin, 2014). In a context where it is necessary to interface with a more dynamic and complex market, entrepreneurship education has become an extremely interesting subject of study as a fundamental element of doing modern business (Vanevenhoven, 2013). In entrepreneurship studies, there have therefore been numerous studies that have focused on the factors that influence entrepreneurship itself, highlighting a close relationship between what is defined as entrepreneurial creativity, with entrepreneurial education (Shahab et al., 2019), just as this last element is related to the development of human capital linked to entrepreneurship and entrepreneurship intention (Passaro et al., 2018), characteristic of subjects who already carry out studies with the precise intention of becoming entrepreneurs (Fayolle & Gailly, 2015). However, entrepreneurial intention can also be formed during studies, thus underlining once again the role of entrepreneurship education in the formation of entrepreneurial behavior (Rauch & Hulsink, 2015). Some studies have focused on the typology of entrepreneurial education concerning studies, differentiating between optional education and compulsory education concerning the training offer, showing how both these typologies contribute to the entrepreneurial skills of students during their training process; however, the impact of entrepreneurship education in compulsory courses is closely related to how students perceive their parents' entrepreneurial performance, thus also highlighting a family

³ University of Napoli Federico II
e-mail: francesco.bifulco@unina.it

influence (Hahn et al, 2020). But a determining factor in entrepreneurship education linked to training courses is also given by the stakeholders on whom the subjects who propose these courses can count, through their involvement, coaching and mentoring, the sharing of experiences and good practices as well as networking (Bischoff et al, 2018). This therefore confirms how Education often makes a difference because it is linked to access to resources and networks (Cannon, 2008). Some studies show that it not only concerns the creation of a business but also affects managerial skills (Albornoz Pardo, 2013). It is also highlighted that entrepreneurship education is an extremely useful tool to reduce gender differences for women with entrepreneurial aspirations, given that, in the context of studies on career intentions, entrepreneurship is still declining as a field “ male” and that women, particularly young women, may limit their career aspirations because they mistakenly believe they do not possess the necessary skills and abilities (Wilson et al., 2007).

Informal Entrepreneurship

Informal entrepreneurship represents a type of business, common globally, which involves the creation and management of the business without it being registered with the competent legal authorities (Mallon & Fainshmidt, 2022). According to the OCED, “informal entrepreneurs are defined as those starting a business or are the owner/manager of a business who engage in monetary transactions not declared to the state for tax, benefit and/or labor law purposes when they should be declared but which are legal in all other respects” (Williams, 2014). The concept of informal entrepreneurship is therefore profoundly linked to that of the informal economy: in informal entrepreneurship, the monetary transactions are all, or largely, not traced, and therefore not declared to the competent authorities, even though they are legitimate goods or services. , given that the conditions described, in the case of illicit goods and services, we are talking about a criminal and non-informal economy, where some populations who do not seem to be predisposed to entrepreneurial dynamics, in reality, are regularizing these businesses would bring economic development to those countries (Williams & Nadin, 2010). If many studies recognize the cost or level of difficulty as the predominant factor in the choice to set up an informal business, other studies instead highlight how the choice is linked, in a more generic way, to the conditions of that market: certainly, the costs of registration and formalization have an impact, but the level of poverty and infrastructure also make the informal aspect more attractive (Siqueira et al., 2016). The level and type of education is also a factor that has a significant impact on the development of informal entrepreneurship, where the presence of secondary and tertiary education favors formal entrepreneurship (Jiménez et al., 2015). However, the university, if supported by correct government policies, can also have a decisive role in attracting economic support for the informal microeconomy (Madichie & Agu, 2023). It is therefore confirmed that the level of quality of political and economic institutions are also factors that influence the type of entrepreneurship, increasing formal entrepreneurship and decreasing informal entrepreneurship (Autio & Fu, 2015), just as the sociodemographic level is closely linked to the level of informal entrepreneurship present (Santos et al., 2021). It is therefore underlined how correct government policies have an impact on informal entrepreneurship, reducing this phenomenon (Omri, 2020). In emerging markets, where the presence of informal entrepreneurship is strong, the very presence of foreign companies and their interaction with local ones is a factor of change towards a greater presence of forms of formal entrepreneurship (Bu & Cuervo-Cazurra, 2020). The factors that influence the development of informal businesses are therefore varied, from access to the market and the role of the family to the sharing of capital and resources, with a view to a true ecosystem of informal entrepreneurship (Igwe et al., 2020). The literature therefore underlines the importance of analyzing this phenomenon. Knowledge of the dynamics linked to informal entrepreneurship can also help managers to better understand the market in which they operate and in particular the nature of a company’s supply chain, thus making it more effective to formulate strategies, but since the informal businesses operate outside the regulatory system, their dynamics and activities are difficult to trace compared to formal businesses (Thai & Turkina, 2014).

Complexity in Female Entrepreneurship

Women’s entrepreneurship (WE) represents a dynamic and multifaceted segment of the global economy. Similar to the broad scope of food delivery, women’s entrepreneurship encompasses a wide range of activities and sectors. This complexity and non-linearity render the topic of women’s entrepreneurship a highly intricate subject for academic study. Brush et al. (2009) define women’s entrepreneurship as the process where women organize all types of businesses, including micro, small, and medium enterprises. Hughes et al. (2012) further expand this definition by emphasizing the role of women entrepreneurs in both formal and informal economies, consequently, this necessitates the redirection of scholarly inquiry towards new directions.

The concept of women’s entrepreneurship is not monolithic but varies significantly across different cultural, economic, and social contexts. De Bruin et al. (2007) highlight the diversity in women’s entrepreneurship, noting that the motivations, challenges, and successes of women entrepreneurs can be vastly different depending on the geographic and socio-economic setting. Minniti and Naudé (2010) add that the complexity of women’s entrepreneurship is also influenced by the differing levels of support and barriers faced by women in various regions like limited market information, low levels of education and skills, and discrimination based on gender and ethnicity are the major barriers that IFE struggle with throughout their business lifecycle (Chiplunkar & Goldberg, 2021).

In recent years, there has been a discernible shift, and scholarly research is increasingly demonstrating the profound impact that innovation is exerting in this domain. Digital platforms have emerged as a critical tool for women entrepreneurs, facilitating market access and business management. Langowitz and Minniti (2007) discuss the impact of

technology on empowering women entrepreneurs, particularly in developing economies. Similarly, Coleman and Robb (2009) explore how online platforms have allowed women entrepreneurs to overcome traditional barriers and access new markets.

Despite the opportunities presented by technology, women entrepreneurs still face unique challenges. The work of Jamali (2009) reveals that women entrepreneurs often struggle with issues such as limited access to funding, societal stereotypes, and balancing work and family responsibilities. These challenges are echoed in the research of Carter et al. (2007), who argue that these barriers can significantly impact the growth and sustainability of women-owned businesses.

The complexity of women's entrepreneurship is further evidenced by its economic impact. Terjesen and Amorós (2010) examine the contribution of women entrepreneurs to economic development and job creation, highlighting the positive effects of supporting women in business. Brush et al. (2012) also emphasize the role of women entrepreneurs in innovating and driving economic growth in both developed and developing countries.

In conclusion, women's entrepreneurship, like food delivery, is a complex and evolving phenomenon. The diverse models and approaches within women's entrepreneurship contribute to its intricacy, making it a non-linear and dynamic field. From the existing literature, it is clear that women's entrepreneurship is not just about starting and running a business; it encompasses a broader spectrum of activities influenced by various socio-economic and cultural factors

Purpose of the paper. This study aims to highlight the importance of a holistic approach that considers the specificities of informal female entrepreneurship and the pivotal role of education in promoting a transition towards more formal and recognized entrepreneurial practices. The research hypothesis is predicated on the role of entrepreneurial education as crucial in providing women with the necessary tools to navigate and thrive in such complex contexts. The cornerstone of this research paper will be the detailed analysis of the case study based on the AWE program, aimed at outlining the dynamics of informal female entrepreneurship and the contribution of entrepreneurial education in facilitating the transition towards formalized and well-structured entrepreneurial activities. The research intends to offer a deeper understanding of how entrepreneurial training can act as a catalyst for the economic and entrepreneurial emancipation of women in contexts marked by complex challenges and opportunities. In summary, this study will contribute to the academic debate on female entrepreneurship and entrepreneurial education, offering practical insights for policies and programs aimed at supporting female entrepreneurs in contexts of high complexity.

RQ: How can entrepreneurial education influence the transition of informal female businesses towards their formalization in complex contexts?

Methodology. Through an exploratory qualitative analysis, this research seeks to analyze the case of the AWE (Academy for Women Entrepreneurs) program, particularly focusing on the edition held in Naples, an initiative dedicated to supporting female entrepreneurship through targeted educational pathways.

Through semi-structured interviews and narrative analysis, tools already employed in the literature on women's entrepreneurship (Garcia, 2013; Topimin et al., 2023), this study will explore the experiences of the participants and organizers of the course. The aim is to understand the type of support offered and the effect that this support has in addressing specific gaps previously dictated by complex starting situations and backgrounds.

The methodology section of this research paper will introduce a structured framework of questions designed to elicit detailed insights into the experiences of participants and organizers within the AWE program.

The interviews encompass a dual-layered approach. The first layer has already been conducted with the program's board in Naples. The second layer of interviews will take place subsequently and will be administered to the same students of the program in order to compare the initial outcomes with the subsequent feedback from the students of the Naples course. The inquiry will explore the diverse backgrounds of the participants and the envisioned development trajectories for their businesses, paying particular attention to the initial conditions and backgrounds that underscore the complexities of their originating contexts.

Identification of the questions of interviews are based on "complexity elements" based on the literature on complexity:

E.1 Social economic barriers (De Bruin, 2007) such as the need to carry out extra-entrepreneurial work to ensure the satisfaction of primary needs. This can limit the time and energy available to engage in entrepreneurial activity

E. 2 Cultural Barriers (Chiplunkar & Goldberg, 2021). Gender stereotypes, social expectations, and discrimination can negatively influence perceptions of women's entrepreneurial skills and limit access to business opportunities.

E. 3 Barriers to accessing support, mentoring, and advice (Minniti and Naudé, 2010). The lack of support networks, both formal and informal, and mentoring opportunities specifically geared toward women entrepreneurs can limit their access to advice, resources, and networking opportunities.

E. 4 Barriers to accessing credit (Jamali, 2009). Gender discrimination can lead to fewer opportunities to obtain loans, investments, or other forms of financial support.

E. 5 Level of knowledge and access to new technologies (Coleman and Robb, 2009). Lack of confidence in using Digital platforms and other technologies has emerged as a fundamental tool for women entrepreneurs that do not facilitate market access and business management.

This table encapsulates the primary questions that will be posed to the participants of the AWE course and the organizing body. The questions are linked to the respective five elements identified previously.

Tab. 1: Key Questions to pose to Learners and Members of the AWE Program in Naples

1. *Socio-economic Barriers: “How do your extra-entrepreneurial responsibilities, such as work to ensure basic needs, affect the time and energy you can dedicate to your entrepreneurial activities?”*
2. *Cultural Barriers: “In what ways have gender stereotypes, social expectations, or discrimination impacted your perception as an entrepreneur and access to business opportunities?”*
3. *Barriers to Accessing Support, Mentoring, and Advice: “Can you describe any challenges you’ve faced in finding support networks, formal or informal mentoring, and advice specifically geared towards women entrepreneurs?”*
4. *Barriers to Accessing Credit: “Have you experienced challenges in securing loans, investments, or other forms of financial support due to gender discrimination? Please share your experience.”*
5. *What challenges have you encountered using digital platforms and new technologies for market access and business management?*

Results. *In the preliminary results, we introduce the main contents of the case study under examination.*

The Academy for Women Entrepreneurs (AWE) gives enterprising women the knowledge, networks and access they need to launch and scale successful businesses.

This program aims to support women in creating and developing entrepreneurial ventures by providing online and onsite training, mentorship, pitch competitions, and networking opportunities. Targeting women between the ages of 18 and 40, AWE emphasizes the importance of innovation and women entrepreneurship on the social or environmental impact of businesses, in alignment with the United Nations Sustainable Development Goals. The program’s three primary objectives are: 1) To offer online educational resources and local support from U.S. exchange alumni, academics, and entrepreneurial leaders. 2) To foster partnerships and collaborations through mentoring, business contacts, and opportunities with Italian and U.S. enterprises. 3) To provide access to a network of Exchange Alumni and resources for women’s economic empowerment.

The selection process of the Academy for Women Entrepreneurs consists of two phases: initially, aspiring entrepreneurs submit a written description and, if they wish, a video of their business project. Subsequently, an oral interview assesses the applicant’s motivation, proficiency in English, digital skills, and the viability of the business idea. Candidates, who may apply individually or as a group, are selected based on the commitment and innovative and sustainable potential of their entrepreneurial proposals.

The primary and most significant aspects of the AWE program and its manifestation in the first Italian edition held in Naples, in collaboration with the University of Naples Federico II, are presented. These initial descriptive findings will be subsequently supported by the outcomes of interviews, which will be conducted as already described in the methodology section.

The Academy for Women Entrepreneurs (AWE) is an initiative of the U.S. Department of State managed in Italy by the University of Naples Federico II, where it also held its first edition.

Building upon the foundational description provided, the remainder of our results will be primarily derived from the responses obtained through interviews with AWE participants, complemented by insights from the program’s organizational members. This qualitative data will illuminate the study in two critical areas:

Firstly, we will delve into which specific dimensions of complexity are perceived to be alleviated through the participants’ engagement with the AWE educational pathway. This exploration aims to identify how the program’s components - spanning online and onsite training, mentorship, and networking opportunities - might reduce the multifaceted challenges women entrepreneurs face.

Secondly, the research will assess the extent to which participation in the AWE program is seen as a catalyst in transitioning toward the formalization of business endeavors. By examining the participants’ perceptions and experiences, this part of the study seeks to ascertain whether the AWE initiative effectively supports women in moving their entrepreneurial projects from the informal to the formal sector.

This structured inquiry is designed to offer a nuanced understanding of the impact of entrepreneurial education in fostering the growth and formalization of female-led enterprises, especially those emerging from complex and diverse backgrounds. Through this lens, we aim to contribute valuable insights into the effectiveness of initiatives like AWE in empowering women entrepreneurs and promoting sustainable economic development in line with the United Nations Sustainable Development Goals.

Research limitations. *In order to investigate how entrepreneurship education can influence the transition of informal women’s businesses towards their formalization in complex contexts, this work analyzed participants in the AWE programme. Although this program is specific to this topic, it takes on a specific aspect also linked to an equally specific territory, where the course is carried out. The work could then be extended by analyzing participants from other similar programmes, in different contexts.*

Managerial implications. *Based on the initial dialogue with the scientific board and the preliminary questions that we posed to them we expect this research to highlight a series of factors linked to informal female entrepreneurship within the analyzed program, attributable to a generic scope of the topic. First of all, to highlight how many participants have never had entrepreneurial experience before. We expect that a substantial number of subjects will have had informal entrepreneurial experiences, which in some cases later became formal. The need for participating subjects to benefit from preparation underlying their activities will be underlined, showing that this could lead to positive impacts on activities*

already underway. We will also highlight the main barriers linked to entrepreneurship, which often discourage the transition from informal to formal: the weight of taxation and bureaucracy should push young entrepreneurs to want to experiment with the dynamics linked to an informal market first, taking on fewer risks on invested capital. Given the complex scenario in which the program participants operate, i.e. that of the South, there should be a lack of skills and competencies capable of exploiting the resources made available by the institutions to face the difficulties of these complex environments: a paradox given that bureaucracy and administrative complexities often prove to be the first obstacles to overcoming the difficulties of these markets. In this sense, the usefulness of programs such as AWE is therefore underlined, capable of allowing formal and informal female entrepreneurs to access resources specifically dedicated to them. As regards informal entrepreneurial activities, the program should develop the will to formalize these activities, seize a greater number of entrepreneurial opportunities, respect the development of a network of stakeholders, and above all respecting being able to receive resources, including economic ones, which can have a strong impact on the growth of their entrepreneurial realities, abandoning a dimension of informality in favor of recognized entrepreneurship

Originality of the paper. Several works have analyzed informal education and entrepreneurship, especially through university-type training courses. This work instead offers a more specific vision, focused on the transition from informal to formal entrepreneurship, through such a training course.

Fostering Entrepreneurial Thinking: Analysing the Drivers and Impact of Entrepreneurship Education

DARIO PEIRONE¹ JUDY SONG²

Abstract

This working paper examines the drivers and impacts of entrepreneurship education on fostering entrepreneurial thinking, focusing on its implementation and outcomes at the University of Turin. As the global economy shifts towards knowledge-based innovation, universities play a pivotal role in promoting entrepreneurship as a key driver for economic growth and sustainable development. The University of Turin exemplifies this transformation by offering programs that engage students in practical, experiential learning scenarios, thereby enhancing their entrepreneurial skills and intentions.

Through a comprehensive literature review, this ongoing study highlights the evolving role of universities in the entrepreneurship ecosystem, emphasizing the significance of entrepreneurship education in facilitating knowledge transfer, innovation, and societal well-being. Employing a unique dataset from the University of Turin, coupled with detailed questionnaires, the study adopts empirical analysis to investigate the effects of various factors—including individual student characteristics and pedagogical approaches—on entrepreneurial intentions and skill acquisition.

The initial findings reveal that while demographic factors such as gender and age have nuanced effects, the educational background, field of study, and pedagogical methods significantly influence students' entrepreneurial outcomes. Practical, hands-on learning experiences are shown to be particularly effective in enhancing entrepreneurial intentions and facilitating the transition from academic knowledge to real-world entrepreneurial engagement. Additionally, the university's entrepreneurial reputation and students' motivations emerge as crucial factors in the successful acquisition of entrepreneurial skills and competencies.

The paper concludes by advocating for a multi-dimensional pedagogical strategy that combines practical insights, motivational clarity, and exposure to real entrepreneurial challenges. This approach is essential for equipping students with the necessary skills and competencies, instilling the confidence and drive to pursue entrepreneurial ventures. The study underscores the importance of inclusive and integrative educational practices in cultivating the next generation of entrepreneurial leaders, contributing to economic growth and innovation. Through its analysis of the University of Turin's entrepreneurship education offerings, this paper offers valuable insights for educators, policymakers, and institutions aiming to foster a more entrepreneurial society.

Key words: *Entrepreneurship, entrepreneurship education*

Framing of the research. *The framework for ongoing research explores the complex interplay between entrepreneurship education and its effects on students' entrepreneurial intentions, activities, and skill acquisition. It emphasizes the crucial role of experiential learning and the influence of individual characteristics, pedagogical approaches, and the entrepreneurial ecosystem in shaping entrepreneurial outcomes.*

The literature review of this area sets a robust foundation, highlighting the evolution of universities into entrepreneurial entities that not only impart knowledge but also act as catalysts for economic development and innovation. The nexus of technology transfer and entrepreneurship underscores the shift towards open innovation and the strategic role of universities in the knowledge economy. Selecting the University of Turin, one of Italy's largest universities, stands out for its comprehensive array of entrepreneurship courses, the diverse backgrounds of its student body, and numerous entrepreneurial initiatives.

The inclusion of comprehensive datasets and descriptive analysis further enriches the study, offering a detailed understanding of the demographic, socio-economic, and educational backgrounds of the participants. This empirical foundation enables a thorough investigation of the variables influencing entrepreneurship education outcomes, providing a solid basis for the econometric analysis.

The ongoing study's focus on the symbiosis between entrepreneurship education and entrepreneurial intention is particularly insightful. It highlights the significant role of education in shaping students' entrepreneurial mindsets and

¹ University of Turin
e-mail: dario.peirone@unito.it

² University of Turin
e-mail: judyyuehling.song@unito.it

intentions, emphasizing the importance of fostering an entrepreneurial culture within the educational ecosystem. The exploration of the distinctiveness of the study, through its focus on psychological, demographic, and educational factors, adds a unique dimension to the research, promising to contribute significantly to the field of entrepreneurship education.

The diverse program description and dataset elucidation provide a clear understanding of the research scope and the specific areas of focus, laying the groundwork for a comprehensive analysis of the impact of entrepreneurship education in the academic environment. This approach not only highlights the institution's role in nurturing future entrepreneurs, but it can also help to create a model for assessing the effectiveness of entrepreneurship education programs.

By integrating theoretical perspectives with empirical evidence, this study promises to contribute significantly to the understanding of how entrepreneurship education can be optimized to support economic growth and innovation, making it a valuable addition to the fields of entrepreneurship, education, and policy development.

The methodological approach, employing an empirical approach by using students' responses and regression analysis—multiple linear regression and logistic regression—allows to get insights on the factors influencing students' entrepreneurial intentions and future entrepreneurship pursuits, as well as to understand the effectiveness of different pedagogical methods.

Purpose of the paper. Moving beyond the conventional emphasis on personal traits, this study expands the analysis to incorporate psychological and demographic factors, thereby providing a richer understanding of the forces driving entrepreneurial aspirations. A novel aspect of our research is the focus on the role of educational programs in enhancing students' entrepreneurial skills, a critical area that has not been sufficiently explored in previous studies.

Adopting a holistic approach, the research evaluates not only the inclination of students towards entrepreneurship but also the interplay of subjective characteristics and personal factors in influencing their entrepreneurial ambitions. This includes examining the significance of educational experiences in equipping students with the skills essential for successful entrepreneurship and evaluating the impact of environmental factors, such as gender and family background, on the efficacy of entrepreneurship education.

The paper further aims to offer a long-term perspective on the outcomes of entrepreneurship education by analysing actual entrepreneurial endeavours undertaken by students' post-education. Through the examination of the entrepreneurship courses at the University of Turin, the study provides valuable insights into the local entrepreneurial ecosystem, underscoring the importance of this research within the context of Italy's academic and entrepreneurial sectors.

Key inquiries addressed in this paper include:

1. The impact of individual characteristics on students' entrepreneurial intentions.
2. The contribution of entrepreneurship education to students' engagement in entrepreneurial activities.
3. The effectiveness of various teaching methods employed in entrepreneurship courses in fostering an entrepreneurial culture.
4. The identification of skills acquired through these courses that prove beneficial for students in their future entrepreneurial pursuits.

Methodology. The ongoing research paper employed data collected based on the questionnaires sent to a total population of 1550 students of which a representative sample of 223 responses was successfully obtained for the empirical analysis of our dataset. The questionnaires employed in this analysis were designed to encompass a wide array of data, (including personal information, educational background, disciplinary specializations, career aspirations, entrepreneurial intentions, acquired skills, entrepreneurial experiences, training received, and university evaluations), following the existing literature addressing entrepreneurial intentions and skills (Hahn et al., 2020; Leung et al., 2012; Hahn et al., 2020).

Additionally, the questionnaire was customized to specifically target students who had completed entrepreneurship training several years prior, encompassing inquiries into whether specific educational backgrounds or individual characteristics correlate with a stronger inclination towards entrepreneurship pursuit.

In our effort to derive meaningful insights from the amassed questionnaire data, we have employed a robust analytical framework leveraging two distinct statistical methodologies: multiple linear regression and logistic regression. This is to delve deeper into the interplay of variables and enhance our capacity for data-driven predictions. We aim to use these statistical tools to shed light on the research questions highlighted in the section of purpose of the paper.

Results. The analysis of questionnaires from the entrepreneurship education programs at the University of Turin uncovers several key insights into student engagement, backgrounds, motivations, and perceptions regarding these courses.

The descriptive findings shows that the DI course, serving as a cornerstone of theoretical entrepreneurship education, has demonstrated its capacity to attract a substantial number of students, indicative of its foundational role and broad appeal. In contrast, the more hands-on SCL and Clab courses, despite their lower enrollment numbers, underscore a distinct student preference for practical, experiential learning, limited by their capacity and entry requirements.

Demographically, the entrepreneurship programs have drawn a diverse cohort of students, spanned a wide age range and included equal genders representation. This diversity reflects the university's capacity to appeal to a broad audience, from undergraduates to postgraduates and professionals, suggesting a widespread interest in entrepreneurship across various stages of educational and professional development.

The study also delves into the socio-economic and familial backgrounds of the students, offering insights into how entrepreneurship education might level the playing field for aspiring entrepreneurs from diverse backgrounds. Despite

the mixed evidence on the impact of family entrepreneurial backgrounds on students' intentions, the data suggests that such education can empower students from all walks of life to explore and engage in entrepreneurial endeavors.

Furthermore, the wide academic diversity among students enrolled in entrepreneurship courses highlights the University of Turin's success in fostering an entrepreneurial mindset across different fields of study. The inclusion of students with prior work experience underscores the proactive nature of these individuals towards entrepreneurship, reflecting the program's role in nurturing entrepreneurial ambitions.

Students' motivations for enrolling in entrepreneurship courses are primarily driven by the desire to acquire practical skills and knowledge, as well as aspirations towards self-employment and autonomy. This indicates that students view these courses as essential stepping stones towards achieving their entrepreneurial ambitions, rather than mere academic exercises.

The assessment of students' entrepreneurial behavior and career aspirations has revealed a strong inclination towards self-employment and entrepreneurial activities. Such findings suggest the effectiveness of the courses in instilling entrepreneurial aspirations and equipping students with the mindset and skills necessary for entrepreneurial success.

Student feedback on the courses has been overwhelmingly positive, particularly praising their interdisciplinary approach, practical insights, and exposure to real-world scenarios. However, the demand for more interactive and practical components within the curriculum points to areas for potential enhancement, ensuring that the programs continue to meet the evolving needs of aspiring entrepreneurs effectively.

Lastly, the findings of the questionnaires show the generally positive perceptions of the university's entrepreneurial ecosystem by the students highlight a supportive environment for entrepreneurship education in the university. Nonetheless, opportunities for further development, especially in external collaboration and international partnerships, could further solidify the University of Turin's reputation as a leader in the field of entrepreneurship education.

The preliminary results derived from our initial regression delve into the intricacies of how various factors influence students' journey through entrepreneurship education, from the initial formation of entrepreneurial intentions to post-training entrepreneurial activities, and ultimately, the acquisition of crucial skills and competencies. Each phase of the regression analysis uncovers preliminary insights into the dynamic interplay between a multitude of influencing variables, providing an early look at the potential pathways through which entrepreneurship education moulds student outcomes.

The first stage of our regression analysis lays the groundwork by examining an expansive set of variables and their influence on students' entrepreneurial intentions. This initial model integrates a wide range of factors, encompassing socio-demographic variables, academic and work experiences, and extends to explore students' motivations for enrolling in entrepreneurship programs. In the exploration into what shapes students' entrepreneurial intentions, our initial analysis reveals that while traditional demographic factors like gender, age, and family background have a role, their impact is subtle. We notice that the educational factors and experiential variables significantly elevate the model's explanatory power, underscoring the critical influence of academic preparation and personal motivations on fostering entrepreneurial mindsets.

Interestingly, parental entrepreneurship does not wield the expected influence, suggesting a departure from the assumed legacy effect in entrepreneurial inclination. Hence, the preliminary nature of these results highlights the complexity of entrepreneurial intention formation, suggesting that both inherent personal traits and the acquired experiences from education contribute significantly to shaping students' entrepreneurial aspirations.

Our second regression model provides early insights into the relatively underexplored area of post-training entrepreneurial activities. Post-training entrepreneurial activities are less about demographic specifics and more about the complex interplay of educational experiences, field of study, and practical exposure. The initial findings suggest that attributes such as the level of education and specific learning experiences within entrepreneurship programs play decisive roles. Practical, hands-on pedagogical methods notably outshine purely theoretical ones in fostering the transition from intention to actual entrepreneurial engagement. The comparison between theoretical and practical approaches reveals a definitive lean towards the efficacy of experiential learning. Practical courses significantly bolster students' likelihood to pursue entrepreneurship, offering tangible skills and real-world insights that theoretical courses cannot match in isolation. This emphasizes the necessity of integrating practical experiences into entrepreneurship education to bridge the gap between academic knowledge and entrepreneurial action.

Our third regression analysis addresses a notable gap in existing literature by focusing on the acquisition of skills and competencies through entrepreneurship education. This initial exploration is particularly important for its emphasis on a critical yet often overlooked aspect of entrepreneurship education—its effectiveness in equipping students with the necessary skills for entrepreneurial success. The determination of acquired skills and competencies underscores a complex interaction between individual characteristics and educational contexts. While gender and educational background exhibit some influence, the broader educational environment, and motivations for engaging in entrepreneurship education emerge as powerful drivers. The significance of the university's entrepreneurial reputation and the targeted motivations for learning new skills highlight the importance of an encouraging, resource-rich educational ecosystem in enhancing skill acquisition. These early insights underscore the importance of a supportive and resource-rich educational environment, as reflected in the perceived reputation of the university, in enhancing the educational outcomes of entrepreneurship programs.

Collectively, these initial regression analyses offer a valuable glimpse into the potential effects of entrepreneurship education on various student outcomes. By presenting these findings as preliminary, we acknowledge the exploratory

nature of our analysis and the need for further research to validate and deepen our understanding of these complex dynamics. These early results serve as a foundation for future investigations into the roles that individual characteristics, educational experiences, and motivational factors play in the broader landscape of entrepreneurship education.

Across all analyses, a common theme emerges entrepreneurship education's effectiveness hinges not solely on imparting knowledge but on creating an integrative learning experience that combines practical insights, motivational clarity, and exposure to real entrepreneurial challenges. This holistic approach not only equips students with the necessary skills and competencies but also instils the confidence and drive to translate entrepreneurial intentions into tangible ventures. The initial findings collectively advocate for detailed understanding of the entrepreneurship education landscape, urging educators, policymakers, and institutions to adopt a multi-dimensional pedagogical strategy that resonates with diverse student aspirations and learning styles.

Research limitations. The study acknowledges certain limitations, including the reliance on self-reported data, which may introduce biases. The specific focus on the University of Turin also limits the generalizability of the findings across different institutional and cultural contexts. Furthermore, the evolving nature of entrepreneurship education and the external economic and social factors influencing entrepreneurial intentions and activities necessitate continuous research in this field.

Managerial implications. The initial findings highlight the importance of integrating practical and experiential learning in entrepreneurship education at the University of Turin, underscoring the potential for such approaches to significantly improve entrepreneurial intentions and activities among students. The findings seem to also suggest that university administrators and educators should focus on tailoring entrepreneurship programs to the diverse needs of students, leveraging the institution's reputation to enhance the effectiveness of these programs. By emphasizing hands-on, real-world experiences and aligning educational offerings with the motivations and backgrounds of students, universities can foster a more robust and inclusive entrepreneurial ecosystem. This approach not only promises to elevate the quality and impact of entrepreneurship education but also serves as a strategic guide for enhancing entrepreneurship skills within the educational domain.

Originality of the paper. The originality of this paper is anchored in its comprehensive examination of the impact of entrepreneurship education, extending beyond entrepreneurial intentions to encompass actual entrepreneurial actions post-training. This exploration not only bridges a notable gap within existing literature but also enriches the dialogue around the practical outcomes of entrepreneurship education. A distinguishing aspect of this research is its investigation into the impact of different teaching approaches, highlighting how varied pedagogical strategies influence skill acquisition and entrepreneurial engagement. Additionally, the study innovatively identifies specific individual characteristics that amplify the effectiveness of entrepreneurial education, offering insights into personalized educational experiences. This dual focus on the tangible outcomes of entrepreneurship education and the interplay of personal attributes and pedagogical methods provides a robust framework for designing more impactful educational programs. Consequently, the paper offers a new perspective on optimizing entrepreneurship education to foster not only intention but also action within the entrepreneurial domain, presenting a complex exploration of the mechanisms through which education catalyses real-world entrepreneurial success.

Students' entrepreneurial intentions among personal and contextual factors: a pilot study exploring the role of emotions.

ROSSELLA BARATTA¹ PIERMATTEO ARDOLINO² DIEGO BELLINI³ SERENA CUBICO⁴
FRANCESCA SIMEONI⁵

Abstract

This study explores the relationship between students' entrepreneurial intentions, well-being, future career anxiety, entrepreneurial education, and entrepreneurial networks.

The literature addressing the antecedents of students' entrepreneurial intentions has already demonstrated the importance of combining both personal and contextual factor. However, among personal factors, emotions have received less attention compared to cognitive factors. Emotions affect how individuals process information and therefore positive and negative emotions have a different effect on decision-making. Well-being, as a positive state of mind, has long been considered as an outcome of entrepreneurship, and the few studies addressing the role of well-being as antecedent of entrepreneurial intentions have led to conflicting results. The literature dealing with the role of negative emotions, such as anxiety, is more limited, and has also provided mixed results. In sum, there is a need to better investigate the role of positive and negative emotions on students' entrepreneurial intentions.

This pilot study aims to address these gaps by investigating the relations between well-being, future career anxiety, educational and social factors, and students' entrepreneurial intentions.

The research involved an online survey administered to a sample of 174 Italian university students. Results reveal the following: future career anxiety predicts entrepreneurial intentions, while well-being does not. Educational and social factors are both strong antecedents of students' entrepreneurial intentions.

These findings shed light on the complex interplay between entrepreneurial intentions, emotions, educational and social factors among university students, providing valuable insights for further research and practical implications for entrepreneurship education and promotion.

Key words: *Entrepreneurial intentions; emotions; well-being; future career anxiety; entrepreneurial networks; entrepreneurial education.*

Framing of the research. *Entrepreneurial intentions (EI) are probably the most significant predictor of entrepreneurial activities and behaviors (Krueger et al., 2000). Given the pivotal role of entrepreneurship for economy and innovation (Barba-Sánchez et al., 2022), scholars have long since begun to study the factors that lead individuals to become entrepreneurs and how their intentions to start or own a business are formed (Krueger et al., 2000). Within this stream of research, consistent attention has been paid to students (Lüthje and Franke, 2003; Zhao et al., 2005; Souitaris et al., 2007; Kuckertz and Wagner, 2010; Wagner, 2012; Krueger et al., 2000; Barba-Sánchez et al., 2022; Maheshwari et al., 2023).*

A recent review of the literature (Maheshwari et al., 2023) has categorized seven main determinants of students' EI, namely cognitive, personality, environmental, social, educational, contextual, and demographic factors. The review also highlighted the dominant role of cognitive factors within this stream of research.

Entrepreneurship, however, is a “highly emotional journey where the heart as well as the mind plays a central role” (Nikolaev et al., 2019, p. 451). Although the role of emotions in enhancing EI has long been neglected by entrepreneurship research (Foo, 2011), more recently scholars have started paying more attention to affect, moods, emotions, and dispositions (Nikolaev et al., 2019). This stream of literature argues that emotions must be incorporated into the factors

affecting EI, because affects and cognition are interrelated (Delgado García et al., 2015). Emotions, both positive and negative, influence decision-making because they influence how individuals process information (Foo, 2011; Chen et al., 2021; Podoyrnitsyna et al., 2012). For example, in entrepreneurship context, emotions are often associated to risk perceptions. Individuals with positive emotions are more optimistic, and positive emotions can lead individuals to make more positive evaluations of a situation and to take more risks (Foo, 2011), while individuals with negative emotions are more likely to favor pessimistic evaluations and judgments, thereby avoiding risks (Chen et al., 2021; Foo, 2011).

Previous research has demonstrated the usefulness of integrating both contextual and personal factors to investigate the broad range of antecedents that influence entrepreneurial intentions, (Lüthje and Franke, 2003; Nabi et al., 2010; Sesen, 2013; Mustafa et al., 2016). The Lüthje and Franke model (LFM) developed by Lüthje and Franke in 2003 (Maheshwari et al., 2023) argues that both personality traits, such as risk propensity and internal locus of control, and contextual factors, such as perceived barriers and support to entrepreneurship, impact students' entrepreneurial intentions. Similarly, the studies by Sesen (2013) and Mustafa et al. (2016) provide evidence that both personality and environment impact students' entrepreneurial intentions. However, these studies have not considered the role of positive and negative moods and emotions within personality factors. Therefore, this study explores the relationship between students' entrepreneurial intentions, well-being, anxiety, entrepreneurial networks, and entrepreneurial education.

The first factor analyzed in this research is well-being. Psychological well-being describes individuals' positive emotions about their overall human functioning (Aldwin and Revenson 1987). In other words, well-being is defined as a positive state which includes emotions such as happiness, optimism, and vitality (Longo et al., 2017; 2018).

Researchers in entrepreneurial studies are increasingly interested in the psychological well-being of entrepreneurs (Ryff, 2019), however, entrepreneurship literature has often considered well-being as a dependent variable (Ryff, 2019; Margaça et al., 2021), and Wiklund et al. (2019, p. 582) defined entrepreneurial well-being as "the experiences of satisfaction, positive affect, infrequent negative affect, and psychological function in relation to the development, start-up, growth, and management of an entrepreneurial venture". In other words, happiness and well-being are a consequence of entrepreneurial activity.

Well-being is an important entrepreneurial outcome, but at the same time, scholars (Margaça et al., 2021; Wiklund et al., 2019) argue that it may also influence the decision to become entrepreneur. Positive emotions significantly impact individual creativity (Baas et al., 2008), problem solving, and innovation (Rhee, 2006; Yuan and Wu, 2020). Moreover, positive emotions can affect the interpretation of ambiguous situation in a positive direction and lead individuals to overestimate the probabilities of positive outcome and to take more risks (Pérez-Fernández et al., 2020; Foo, 2011). Indeed, research has found that positive moods and emotions, such as optimism, are positively related to students' entrepreneurial intentions (Hernández-Sánchez et al., 2020).

Previous research dealing with entrepreneurship and well-being has noted that well-being can be the antecedent of several important work-related outcomes, such as: productivity (Donald et al., 2005), creativity (Baron and Tang, 2011) and cooperation in the workplace (De Neve et al., 2013).

However, the limited research investigating well-being as a driver of EI has found conflicting results. Some studies have found that students' well-being positively influences their entrepreneurial intentions (Routledge et al., 2021; Sahrah et al., 2023). However, other research has revealed that subjective well-being only indirectly affects entrepreneurial intentions (Contreras-Barraza et al., 2022) or that psychological well-being mediates the relation for female but not for male (Margaça et al., 2021). In addition, other studies found insignificant (Chen et al., 2021) or even negative (Zhang et al., 2015) relations between well-being and entrepreneurial intentions. In this regard, the work by Foo and colleagues has showed that sometimes it is the lack of well-being to enhance the decision to start a business (Foo, 2011; Foo et al., 2009). Similarly, Nikolaev et al. (2019) found that individuals with positive moods and emotions generally do not want to change their life and to enter risky situations.

The second factor analyzed in this research is future career anxiety. Anxiety is defined as a state of mental feeling of tension and worries about the future (Banerjee, 2020). Anxiety is identified as a negative emotion, which lessen intentions to carry out a specific action in several types of behavior, because general fear and anxiety can determine self-efficacy reduction (Arora et al., 2021) and insecure and anxious individuals are generally more uncertain of their ability to address threats (Zelekha et al., 2018).

Previous research has indicated that anxiety influences career development and plays a crucial role in career decision making (Chang, 2011; Tsai et al., 2017). For example, Meredith et al. (2007) found that anxious individuals choose careers mainly on salary criteria, even though this may cause them to experience lower career satisfaction.

As Baron (2008) highlighted, entrepreneurs often navigate environments marked by complexity and uncertainty, which can predispose individuals to negative emotions that tend to promote pessimistic evaluations and risk avoidance (Foo, 2011). Furthermore, these negative emotions can impede the identification and exploitation of business opportunities (Shepherd et al., 2015; Doanh et al., 2021). Consequently, it is possible to argue that future career anxiety may also influence students' entrepreneurial intentions. In the literature, few studies have focused on perceptions derived from an unsafe, dangerous, and risky environment, and the impact these perceptions can have on the intention of starting a business (Hernández-Sánchez et al., 2020).

Pérez-Fernández et al., (2020) found that negative affective traits negatively influence attitudes towards entrepreneurship, however they do not include intentions in their analysis. Zelekha et al. (2018) found that the less anxious an individual is, the more entrepreneurial tendencies he will express. More recently, anxiety and fear have been studied in relation to the Covid -19 pandemic. Mahmud et al. (2020) found that due to the outbreak of pandemic people are

becoming depressed and anxious about their future career. Doanh et al., (2021) found that the fear and anxiety of Covid-19 can reduce entrepreneurial self-efficacy, entrepreneurial intention, and entrepreneurial behavior.

However, other research has found insignificant relations between future career anxiety and students' entrepreneurial intentions (Baratta et al., 2021), and some studies have found that anxiety can even enhance the intention to start a business. In this sense, anxiety can be associated with heightened perception and alertness that can activate people to engage in reward-seeking behavior (Kashdan and Biswas-Diener, 2014). Nikolaev et al. (2019) found that individuals who are high on negative dispositional affect are more likely to engage in entrepreneurial action. In this sense, entrepreneurship can be potentially appealing for people who want to change their life for the better, even entering risky situations. More recently, Bhardwaj (2024) found that both positive emotions and fear of failure determine entrepreneurial intentions.

In sum, research investigating the role of emotions as a driver of EI is still limited. Scholars (e.g., Wiklund et al., 2019; Margaça et al., 2021; Chen et al., 2021) call for more study on the antecedents and consequences of entrepreneurship related to positive emotions, such as well-being. Moreover, most of entrepreneurship literature to date has focused on positive emotions, largely ignoring the negative ones (Nikolaev et al., 2019). The limited research on fear and anxiety have also provided mixed results, and scholars (e.g., Chen et al., 2021; Nikolaev et al., 2019) argue that combining positive and negative feelings will better reflect the influence of emotional factors on EI.

Given the usefulness of combining both personal and contextual factors (Lüthje and Franke, 2003), the current research also investigates the role of educational and social factors. Contextual factors, such as perceived social and institutional support, family characteristics and expectations, network ties, perceived barriers to entrepreneurship (Steele, 2004; Lüthje and Franke, 2003; Liñán and Fayolle, 2015), as well as the level and quality of education and training on business, job placement and entrepreneurship (Zhao et al., 2005; Baum et al., 2007; Soiutaris et al., 2007; Kuckertz and Wagner, 2010) have long been studied as antecedents of students' EI.

The third factor analyzed in this research is entrepreneurial education. Although some studies found weak or insignificant relations (Sesen, 2013; Mustafa et al., 2016) between university environment and entrepreneurial intentions, previous research has nevertheless emphasized the role of entrepreneurial education and training because entrepreneurial education can enhance both entrepreneurial knowledge and skills (Brüne and Lutz, 2020). Moreover, individuals that received formal learning on entrepreneurship in their academic activities are generally given the opportunity to observe successful business models, they are exposed entrepreneurs' lectures and case studies, and therefore are expected to display higher levels of entrepreneurial self-efficacy (Zhao et al., 2005).

The fourth factor analyzed in this research is entrepreneurial networks. Social factors play a significant role in fostering students' entrepreneurial intentions. Although some research indicated that social networks are less significant than personality factors in affecting entrepreneurial intentions (Sesen, 2013), nevertheless involvement in and exposure to entrepreneurial networks, whether through familial connections or acquaintances, are recognized as crucial antecedents to entrepreneurship (Maheshwari et al., 2023). In this context, the family's influence has been underscored in various studies. Notably, students hailing from entrepreneurial backgrounds and with prior family exposure to entrepreneurship generally exhibit heightened intentions towards entrepreneurship (Carr and Sequeira 2007; Liñán and Fayolle, 2015).

Purpose of the paper. Given the aforementioned literature, this pilot study explores the relationship between students' entrepreneurial intentions, well-being, future career anxiety, entrepreneurial networks, and entrepreneurial education. By doing so, the study aims to add to current literature on entrepreneurial intentions by combining both personal and contextual antecedents of entrepreneurial intentions (Lüthje and Franke, 2003). Moreover, this study aims to fill a gap in the literature by incorporating the role of both positive and negative emotions as personal factors (Nikolaev et al., 2019). Specifically, the aim of the study is to test the following hypotheses:

- H1: Students' positive emotions, such as well-being, are related to entrepreneurial intentions.
- H2: Students' negative emotions, such as future career anxiety, are related to entrepreneurial intentions.
- H3: Students' education on entrepreneurship is positively related to entrepreneurial intentions.
- H4: Students' entrepreneurial networks are positively related to entrepreneurial intentions.

Methodology. To test the research hypotheses, an online survey was developed.

Entrepreneurial intentions were measured using a 6 items scale (My professional goal is to become an entrepreneur), similar to the operationalization of Lüthje and Franke (2003) and Kuckertz and Wagner (2010). The scale possesses excellent internal reliability and Cronbach's $\alpha = .96$.

Well-being was assessed using the short version of the Scale of General Well-being (Longo et al., 2017; 2018). The scale comprises 14 items, namely: happiness, vitality, calmness, optimism, involvement, self-awareness, self-acceptance, self-worth, competence, development, purpose, significance, congruence, and connection. The scale display excellent internal reliability as Cronbach's $\alpha = .90$.

Future career anxiety was measured using a 5 items scale originally developed by Tsai et al., (2017) in order to assess students' future career anxiety (I worry about future employment because of a potential economic recession). Internal reliability is excellent and Cronbach's $\alpha = .94$.

Entrepreneurial education was measured with 2 items, dealing with the level of training and education received during the study path. Cronbach's $\alpha = .72$, which is lower but still acceptable (Nunnally, 1978).

Entrepreneurial networks were assessed as a dummy variable, with 1 indicating the presence of entrepreneurs in students' social network (family and friends), and 0 indicating the absence of entrepreneurs in students' social network (family and friends).

All questions, except for entrepreneurial networks, were assessed using a 5-point Likert scale ranging from 1 – strongly disagree to 5 – strongly agree.

The pilot sample includes 174 Italian students. The majority of respondents are female (94%), the average age is 23; 58% are undergraduate students, while 42% are graduate students; 48% are working students.

Results. Descriptive statistics are reported in Table 1. Students' EI are quite low on average, as well as EDU. However, it is important to mention that the majority of surveyed students do not attend Business and Economics courses. Students' WB is quite high, and higher than FCA. Half of the sample belongs to an entrepreneurial network (family or friends).

Table 1. Descriptive statistics

	Mean	SD
EI	2.07	1.02
WB	3.39	.63
FCA	2.76	1.14
EDU	1.96	.89
	N	Frequency
Net	87	50%

The correlation matrix (Table 2) shows that EI are positively correlated with FCA, EDU and Net. Notably, WB and EI are not correlated.

Table 2. Correlation matrix

	EI	WB	FCA	EDU	Net
EI	1				
WB	0.051	1			
FCA	0.183*	-0.134	1		
EDU	0.566**	0.038	0.14*	1	
Net	0.258**	0.107	-0.084	0.165*	1

Note: * $p > 0.01$; ** $p > 0.001$

To better assess the role of entrepreneurial ties, an independent samples *t* test was conducted (Table 3). The sample was divided into two subsamples based on the presence of entrepreneurs in students' social networks (= 1, 50%). Results show that students belonging to entrepreneurial networks display higher EI and more EDU.

Table 3. *T* test on entrepreneurial networks

	Group	Mean	Std. Deviation	S.E. Mean	Sig. (2-tailed)	
EI	1	2.33	1.11	0.12	0.001	
	0	1.81	0.86	0.09		
WB	1	3.46	0.62	0.07	0.161	
	0	3.32	0.65	0.07		
FCA	1	2.66	1.13	0.12	0.270	
	0	2.85	1.14	0.12		
EDU	1	2.1	0.95	0.1	0.030	
	0	1.81	0.81	0.09		

Then an independent samples *t* test on students' EI was conducted (Table 4). The sample was divided into two subsamples based on EI. As the mean value of EI = 2.07 and the median value = 1.82, the cutoff was set = 2. Results show that students with higher EI (≥ 2 , 46%) display more EDU, more FCA and more Net. WB does not show significant differences in means.

Table 4. T test on entrepreneurial intentions

	Group	Mean	Std. Deviation	S.E. Mean	Sig. (2-tailed)
WB	≥ 2.00	3.35	0.62	0.07	0.394
	< 2.00	3.43	0.65	0.07	
FCA	≥ 2.00	3.01	1.11	0.12	0.006
	< 2.00	2.54	1.12	0.12	
EDU	≥ 2.00	2.42	0.91	0.1	0
	< 2.00	1.56	0.66	0.07	
Net	≥ 2.00	0.59	0.5	0.06	0.033
	< 2.00	0.43	0.5	0.05	

In order to test the research hypothesis, a multiple regression was conducted. This method allows to analyze the simultaneous influence of independent variables, considered predictors, on a dependent variable (Hair, 2011). As reported in Table 5, results show that FCA, EDU and Net significantly affects students' EI. WB displays an insignificant relation. These results confirm H2, H3 and H4, while H1 is not supported.

Table 5. Multiple regression on entrepreneurial intentions

Variable	t	Sig.
(Constant)	0.59	0.557
WB	0.48	0.632
FCA	2.07	0.004
EDU	8.20	0.000
Net	2.88	0.005

Note: R = 60, R2 = 0.36, adj. R2 = 0.35

Research limitations. This pilot study constitutes only a part of a broader and continuously evolving research project. The main limitations of the current study pertain to its sample size and composition. For instance, the sample predominantly comprises female students, with an absence of representation from business and economics disciplines, among other factors. Additionally, this research solely delves into the examination of specific factors' influence on EI, yet the literature indicates the existence of numerous other variables that have an impact on the decision to start a business.

Managerial implications. Given the pivotal role of entrepreneurship in fostering economic growth, driving innovation, and enriching society (Barba-Sánchez et al., 2022), it is imperative to cultivate entrepreneurial activities and enhance students' EI. The findings of this research provide practical implications for entrepreneurship education and promotion.

- Enhance formal learning and education on entrepreneurship. Incorporating entrepreneurship education into the curriculum could be beneficial, as it can equip students with the necessary knowledge and skills to pursue entrepreneurial ventures. This could involve offering courses, workshops, or mentorship programs aimed at fostering entrepreneurial mindsets and abilities.
- Facilitating networking opportunities for students within entrepreneurial communities or among successful entrepreneurs could help cultivate supportive social networks conducive to entrepreneurial endeavors. This could involve organizing networking events, guest speaker sessions, or alumni mentorship programs.
- Recognizing the positive relationship between anxiety and entrepreneurial intentions suggests that anxiety itself may not necessarily be a barrier to entrepreneurship but rather a potential catalyst for motivation and action. By addressing anxiety and providing appropriate support mechanisms, educators and support organizations can help students harness this energy and leverage it to pursue their entrepreneurial goals more effectively.

Originality of the paper. This research shed light on the complex interplay between entrepreneurial intentions, positive and negative emotions such as well-being and anxiety, and contextual factor, such as education and social networks. In doing so, this study contributes to existing research on entrepreneurial intentions in two ways:

- First, it supports the relevance of combining both personal and contextual factors (Lüthje and Franke, 2003). Contrary to previous research (Sesen, 2013; Mustafa et al., 2016) however, our findings demonstrate that contextual factors have a stronger impact than personal ones in enhancing students' intentions to start a business.
- Second, this study incorporates the role of emotions within personal factors. While previous studies have primarily concentrated on positive emotions (Chen et al., 2021; Nikolaev et al., 2019), this research broadens the scope by analyzing the concurrent impact of both positive and negative emotions on students' entrepreneurial intention. By including negative emotions such as future career anxiety, this study aims to provide a more nuanced understanding of the emotional landscape influencing entrepreneurial aspirations.

Social Entrepreneurship and Sustainability. How can challenge-based learning impact students' entrepreneurial skills and challenge providers' problems?

ALESSANDRA SCROCCARO¹

Abstract

The Department of Economics and Management of the University of Trento offers a master's Course, Sustainability and Social Entrepreneurship, which focuses on hybrid and sustainable companies and aims to transfer the ability to examine opportunities and challenges for promoting corporate and nonprofit/hybrid corporate responsibility and sustainability. The 48-hour Course (8 ECTS) aims to impart knowledge, skills, competencies, approaches, and techniques specific to social impact business design. It also seeks to understand current challenges, trends, and future scenarios in sustainability, innovation, and social entrepreneurship, as well as the main business models available for creating social impact. It is a challenge-based and hands-on course that includes developing a project idea and a social business model to be presented at the end of the Course, starting from challenges launched by the so-called challenge providers in the Trentino territory (such as organizations, cooperatives, and associations). By immersing themselves in the challenges, the students respond to concrete problems, presenting innovative and sustainable solutions at the end of the Course. The purpose of the paper is to understand how an educational initiative such as this Course impacts in two ways: one way is the educational learning, by increasing students' entrepreneurial and innovation skills, and on the other way, how it can have an impact on challenge providers. To evaluate the impact of the challenge from the perspective of students, the research collects data through EntreComp, the European Framework survey concerning entrepreneurial skills. The survey is submitted to students at the beginning and end of the Course. The research also collects data from the reflective tools. To evaluate the impact of the challenges from the perspective of the challenge providers, the research collects data from semi-structured interviews. Preliminary results gathered from the EntreComp and the reflective tools show that students increase their entrepreneurial skills such as, among others, the identification of opportunities, creativity, the capacity to mobilize teammates, problem-solving, and communication skills. From the challenge providers' perspective, this Course represents an opportunity to acquire new ideas and solutions, recruit young talents, and gain knowledge and competencies.

Key words: social entrepreneurship; sustainability; challenge-based learning; social innovation; social economy; higher education

Framing of the research. *The Department of Economics and Management of the University of Trento offers a master's Course, Sustainability and Social Entrepreneurship, which focuses on hybrid and sustainable companies and aims to transfer the ability to examine opportunities and challenges for promoting corporate and nonprofit/hybrid corporate responsibility and sustainability. The 48-hour Course (8 ECTS) aims to impart knowledge, skills, competencies, approaches, and techniques specific to social impact business design. It also seeks to understand current challenges, trends, and future scenarios in sustainability, innovation, and social entrepreneurship, as well as the main business models available for creating social impact. Through developing knowledge related to social entrepreneurship and third-sector management, the Course aims to analyze the spaces, tools, and opportunities for the strategic development of Third Sector organizations, the cooperative world, nonprofit companies, and B-Corp, focusing on new forms of social innovation.*

It is a challenge-based and hands-on course that includes developing a project idea and a social business model to be presented at the end of the Course, starting from challenges launched by entities, the so-called challenge providers in the Trentino territory (such as organizations, cooperatives, and associations). By immersing themselves in the challenges, the students respond to concrete problems, presenting innovative and sustainable solutions at the end of the Course.

The Course aims to stimulate transversal skills, which are also the 15 entrepreneurial skills outlined by EntreComp, the European framework, divided into three macro areas: the ability to identify ideas and opportunities, knowing how to mobilize helpful resources to solve problems and generate solutions, and finally knowing how to manage a project.

At the end of the Course, students should be able to:

¹ University of Trento
e-mail: alessandra.scroccaro@unitn.it

- Understand the general concepts related to sustainability, innovation, and social entrepreneurship;
- Identify and describe the main models of social entrepreneurship and social innovation;
- Recognize the main managerial approaches to transform social entrepreneurial opportunities into business models and to develop socially innovative ideas and solutions;
- Analyze and evaluate how social entrepreneurship and social innovation enable sustainability and how social entrepreneurs can act as change agents;
- Analyze the needs and funding sources for social entrepreneurship and social innovation;
- Analyze a problem, putting it in context, identifying key stakeholders, and understanding customer/user needs;
- Generate innovative and sustainable social impact solutions;
- Understand social impact design, measurement, and evaluation;
- Present a pitch in front of an audience consisting of faculty, investors, and Third Sector organizations.

Purpose of the paper. *The purpose of the paper is to understand how an educational initiative such as this Course impacts in two ways: one way is the educational learning, by increasing students' entrepreneurial and innovation skills, and on the other way, how it can have an impact on challenge providers. The challenge-based approach applied to real problems can lead to change by substantially impacting companies and organizations that offer challenges to be solved. Also, this innovative learning method leads to capacity building, soft skills or 21st-century skills acquisition, and experiential and active learning that connects students with companies, cooperatives, and Third Sector organizations.*

Methodology *To evaluate the impact of the challenge from the perspective of students, the research collects data through EntreComp, the European Framework survey assessing entrepreneurial skills. The survey was submitted to students at the beginning and end of the Course. The research also collects data from the reflective tools used during the Course, such as individual learning agreements and individual reflection reports based on Kolb's approach and Gibb's reflective cycle. To evaluate the impact of the challenge from the perspective of the challenge provider, the research collects data from semi-structured interviews.*

Results. *Preliminary results gathered from the EntreComp and the reflective tools show that students increase their entrepreneurial skills such as, among others, the identification of opportunities, creativity, the capacity to mobilize teammates, problem-solving, and communication skills. From the challenge provider perspective, this Course represents an opportunity to acquire new ideas and solutions, recruit young talents, and gain knowledge and competencies.*

Research limitations. *The students' sample is limited in number. A longitudinal study is not currently possible since this is the first edition of the course.*

Managerial implications. *The paper gives extensive details on designing and managing a challenge-based course to have a coherent and efficient entrepreneurship education initiative.*

Originality of the paper. *The paper contributes to applying challenge-based learning into entrepreneurship education literature, giving two perspectives and studying the impact on the students' learning, specifically on their entrepreneurial skills and the challenge providers' outcomes.*

Humane entrepreneurship and the circular economy: an empirical investigation

MASSIMILIANO VESCI¹ ROBERTA DE ANGELIS²

Abstract

This study examines the Humane Entrepreneurial Orientation (HEO) key characteristics in the field of Circular Economy (CE) investigating Entrepreneurial Orientation (EO), Sustainability Orientation (SO), and Humane Resource Orientation (HRO) in two Italian SMEs presenting circular business models (CBMs). The study contributes to the nascent literature of CE offering evidence of the and Humane Entrepreneurship (HumEnt) approach. Results expands the body of knowledge of EO, SO, and HRO features boosting the discussion among scholars and building blocks toward the betterment of the HEO measurement.

Key words: *Humane Entrepreneurial Orientation; Circular Business Models; Case Studies; Italy.*

Framing of the research. *Humane Entrepreneurship (HumEnt) has been conceived as a behavioral and attitudinal theory of entrepreneurship that extend the entrepreneurial strategic behavior outlined by Covin and Slevin (1989). In particular, drawing on entrepreneurial orientation theory (Covin and Lumpkin, 2011), two different HumEnt models can be detected in literature. Model 1, proposed by Kim et al. (2018), emphasizes the role of human resources and sustains the need to integrate the entrepreneurial within a specific human-centered logic (Kim et al., 2021). Model 2, proposed by Parente et al. (2018, Parente et al., 2021), defines the pivotal entrepreneurial strategic posture of Humane Entrepreneurial Orientation (HEO) as “the extent to which entrepreneurs and top managers are inclined to take care of a firm’s competitiveness, to take care of their human resources and to take care of relevant social values and concerns, including those regarding environmental sustainability” (Parente et al., 2021, p. 512). Given the fact that how to move towards a more environmentally and socially sustainable economy is a long-debated issue, HumEnt seems to represent an essential framework to understand current times and analyze the emerging business models. In fact, HumEnt has been supposed to be strictly related with entrepreneur’s inner values and culture, regulatory rules, operated business, etc., thus having also the potential to boost the transition toward an enlargement of corporation’s main purposes suggested from the Business roundtable (2019). In this paper, HumEnt is examined within the context of businesses implementing circular economy principles in their business models. The circular economy (CE) has catalyzed interest across different quarters recently including policy, business and academic circles for its potential to address multiple sustainability challenges and build a more resource efficient and resilient economy (Kirchherr et al., 2023). Academically, the research on the CE has been proliferating. Authors in this field have conducted extensive literature reviews (e.g., Ghisellini et al., 2016; Ludeke-Freund et al., 2018); they also examined circular business models (e.g., Hopkinson et al., 2018) as well as the relationship between the CE and the United Nation’s Sustainable Development Goals (e.g., Schroeder et al., 2018). Others have explored drivers and barriers to CE implementation (e.g., Govindan & Hasanagic, 2018), application across different contexts (Katz-Gerro & Sintas, 2019), its conceptualization (e.g., Kirchherr et al., 2017) and circularity indicators (Kristensen & Mosgaard, 2020) among other themes. Yet, there are only few studies at the intersection between the entrepreneurship and the CE literature (Re & Magnani, 2022; Zucchella & Urban, 2019).*

Purpose of the paper. *Whilst contributions to these emerging research areas (HumEnt and CE) have been growing rapidly, the literature exploring HumEnt within the CE context is just nascent (Ghisellini et al., 2021; Le, 2022), and in the case of HumEnt contributions have remained at theoretical level in most cases (Kim et al., 2018; Parente et al., 2018; 2021). Thus, more empirical evidence in the realm of business is strongly needed trying to understand how HumEnt values are implemented in business context in particular in the CE. By applying the HumEnt framework, this study attempts to shed light on the CE phenomenon having as its goal the framing of HEO’s characteristics by showing how firms operating in the CE have implemented the HumEnt approach. Using a qualitative methodology and drawing on insights from two case studies (namely, two Italian SMEs), this study attempts to investigate how the HEO’s dimensions have been interpreted, answering the following research question:*

RQ1. How are the characteristics of HEO strategic posture framed in circular small and medium enterprises?

¹ University of Salerno
e-mail: mvesci@unisa.it

² e-mail: DeAngelisR@cardiff.ac.uk

HEO is described by three dimensions: EO, SO and HRO that are supposed to be part of the firm's business model, strategy and possibly values (Parente et al., 2018, Parente et al., 2021).

Methodology. This research is based on qualitative case studies (Yin, 2014). Qualitative case studies are a common research approach in the empirical literature on circular business models (e.g., De Angelis & Feola, 2020) and HEO (e.g., Vesci et al., 2023; Buratti et al., 2022). Therefore, our research approach is appropriate in the context of this study because both CE and HumEnt are in their early stage, and thereby, could benefit from the insights generated through qualitative research. Purposive logic (Miles and Huberman, 1994) has been used to select our case studies, which means that cases are included because they are relevant from the perspective of this study. The selection of the cases was guided by the circularity measures highlighted in the ReSOLVE framework (EMF et al., 2015), which includes: Regenerate, Share, Optimise, Loop, Virtualise and Exchange (ibid.). These measures mirror CE principles and particularly: 'Eliminate' waste and pollution by design, 'Circulate' materials and components that sit within products and 'Regenerate' natural systems (ibid.). The findings we illustrate are anonymized to comply with the ethical procedure followed in this research.

Alpha and Beta are two Italian companies operating respectively in refurbished electronic devices and packaging sector. Alpha is a SME operating in both B2B and B2C context. Alpha buys directly electronic devices (in particular, iPhones, iPads, and Macs), putting them back on sale at the end of a careful process of regeneration that is divided into three phases: testing (ascertain the actual status of the electronic device), laboratory (repairing), and grading (electronic device grading based on its new status). To date, Alpha has refurbished more than 30.000 electronic devices promoting a smarter and more intelligent approach to consumption. Alpha is an example of a company operating in the 'technical cycle' of the CE espousing the 'Share' and 'Loop' measures in the ReSOLVE framework (EMF et al., 2015). Beta is an SME operating in the eco-design and architecture sector by designing sustainable corrugated cardboard products. In particular, Beta realizes displays, furnishings, communication supports and special packaging that are mainly made with interlocking techniques and without the use of glues. Water-based inks, sophisticated cutting and printing techniques guarantee minimal environmental impact. To date, Beta has realized furnishings entirely in cardboard for restaurants and museums, trade fair stands entirely made of recycled and recyclable cardboard, etc. Beta is an example of a company operating in the 'technical cycle' espousing the 'Optimise and 'Loop' measures in the ReSOLVE framework (EMF et al., 2015).

Both secondary data and primary data (semi-structured interviews) have been collected. Interviews were conducted between October 2022 and March 2023 by one of these authors. The interviews lasted approximately 120 minutes in total, were conducted on-line, digitally recorded and professionally transcribed. Italian interviews were then translated in English by one of these authors. The interviews were conducted with key informants, i.e., those with substantial and exclusive information (Aguinis and Solarino, 2019,) and particularly with the marketing officer for company Alpha and the president and founder for company Beta, so that the questions could be addressed to gain rich data (Creswell, 2012). The interviews were based on questions informed by the CE and circular business models literature as well as HumEnt framework. Data collection was deemed complete at the point of saturation, i.e., when there were no new insights emerging from the process of data collection (Bowen, 2008).

The findings here illustrated emerge from our own data analysis and interpretation and thereby, they fall exclusively under our responsibility.

Results. To ascertain the characteristics of the HEO strategic posture in circular firms, this study employs the HEO framework (Parente et al., 2021; Vesci et al., 2023) which has been chosen for its comprehensiveness in describing HumEnt approach identifying all the elements whose presence is necessary to recognize the high level of strategic posture aligned with HumEnt prescriptions. Particularly, the elements that make up this framework are: Entrepreneurial Orientation, Sustainability Orientation, and Humane Resource Orientation (Parente et al., 2021; Vesci et al., 2023). Next, we briefly illustrate the characteristics of these components for the organizations involved with this study.

Entrepreneurial Orientation

Entrepreneurial Orientation, expressing to which extent firm's strategic posture could be considered entrepreneurial or, in contrast, conservative, includes predominantly three subdimensions (Wales et al., 2013; Rauch et al., 2009): risk-taking, innovativeness and proactiveness as traditionally described by Covin and Slevin (1989).

Risk Taking

For Alpha: "[This is] such a [risk-oriented enterprise]. We believe a lot in this [business] for a simple reason: because in distribution, credibility and the fact of having created it over the years are very important. It is the thing that currently moves operations the most. [...] A new player who wants to enter the distribution sector will have to face many barriers which are certainly linked to the availability of cash flow but also to the willingness to take [other types of] risks. Since we have a very strong network, we can trust our suppliers, just as we are reliable suppliers for third parties. This means that we eliminate the risk or in any case we greatly reduce the risk of accidents, [running the business]". [Alpha's Marketing Director, Interview 1 extract].

For Beta: "there are many types of risks beyond financial risk: outside, there are many things. There are many black swans that come: once Covid came; [...] now this madman has come along and has started the war that has blocked everything. We must also be quite resilient". [Beta's President and Founder, Interview 1 extract].

Innovativeness

For Alpha: “[This company is] very [innovative] in the sense that, as I was saying, we are investing in technology and I’m pleased, in short, [...] to talk about it, because the difference between a new product and a refurbished one is the workmanship and therefore the credibility. [...]. We are investing a lot in technology and therefore innovation is one of the cornerstones. [Innovation] can also take the form of training [...] I don’t know if you were more specific about technological innovation, though! In general, [training and technological education] is an asset [...]. Having technicians that no one else has [...]. Clearly, therefore, also investing in training [means] investing in innovation in a broader sense”. [*Alpha’s Marketing Director, Interview 1 extract*].

For Beta: “Lightness and performance of the paper. This was the innovation we put in. [...] Our main role is to provide customers with innovative solutions for different packaging, which must also be attractive, must be pleasant and the innovation has been made. [...] Everyone makes products but few communicate how the product is made and this is innovation, because obviously the material that you purchase as raw material, even if perhaps recycled, must have specific characteristics, [...] it must be existing, it must be beautiful, it must be clean, it must be everything, but it must also be made with sustainability standards, [...]. Innovation can be product innovation, it can [mean] bringing workers together or [valorising]. those who have said they are doing something new; innovation means looking ahead and seeing what product our customer needs”. [*Beta’s President and Founder, Interview 1 extract*].

Proactiveness

For Alpha: “[Alpha is a] very [proactive company] in the sense that the attention is always there. [...]. Yes, [we made some choices anticipating what then happened in economic scenario], if we are talking about the choice of having the objective of being the company that is the leader in Italy in the field of distribution for this specific refurbished product. [...] This in itself is already a courageous choice. Even before the e-commerce boom there was this definite interest. [...] Abroad there was already much more confidence with online purchases and with the refurbished products. In Italy, refurbished goods were very rarely requested: if in fact, for example, you do a search on Google [about refurbished products and] the keywords searched by users, in the last 2-3 years, [you can see] a huge growth in the last 2-3 years”. [*Alpha’s Marketing Director, Interview 1 extract*].

For Beta: “Moments [of difficulty] may occur because, for example, our customers have less money available to make purchases. Packaging that has a certain cost, display packaging I mean, becomes a superfluous purchase. And this could be a dangerous [for my firm]. [...] There are many of us working in the same direction to develop this business. [...] And therefore we must understand, see the market and give it [what the customer asks for, what] it needs. Calmly, with serenity, without panicking. [...] privileges sooner or later finish; [Let’s stick] to normal things, not to privileges”. [*Beta’s President and Founder, Interview 1 extract*].

Interviews’ results show that differently from Miller (1983, 2011) and Covin and Slevin (1989) that measured: (1) innovativeness predominantly in term of the new products created by the firm; (2) risk-taking as, “the degree to which managers are willing to make large and risky resource commitments - i.e., those which have a reasonable chance of costly failures” (Miller and Friesen, 1978, p. 923); and (3) proactiveness as a forward-looking perspective associated with grasping new opportunities and introducing innovative activities, in the two investigated cases Innovativeness has been associated with training and technological education (Alpha), technology innovation to boost product’s performance (Alpha and Beta) and only finally new products (Beta). Similarly, in the case of risk-taking, both firms, recognizing that risk is strictly associated with cash (and thus is a financial issue), seem to conceptualize the broader concept of entrepreneurial risk identifying ways to face it mentioning entrepreneurial credibility (Alpha), or resilience to manage the business environment (Beta). Only the proactiveness subdimension is completely in line with Covin and Slevin’s (1989) conceptualization as a forward-looking perspective anticipating bad things (Beta) or having the courage to make choices not necessarily in line with the common competitors’ acts, i.e. doing in advance what will occur in the near future (Alpha).

Sustainable Orientation

SO is in HumEnt approach is interpreted as the exhibition of high level of commitment to the preservation of the environment but also in terms of acts to improve the quality of life in the local community (Parente et al., 2021. In this sense, it can be measured by referring to the degree to which the firm “strategically realizes projects (1) to improve the quality of life and the well-being of the local community, and (2) to protect or restore the environment (Vesci et al., 2023, p. 570).

For Alpha: “The direction is to have a strategy that allows us to quantify what our impact is on the environment in the future. At the moment we do it (...) in the sense that we know that [...] we have allies who are equally aware. I’m talking about shipping for example: X is a partner that pays a lot of attention among all couriers, for example to these issues. [...] I would add that [the strategy and] the value proposition [...] is to have strong control of the supply chain. So, we can [...] have access to large stocks at favorable prices. [...] “At the moment we are doing projects with “XXX” (which is a local

company) and with which we are actively trying to create, for example, events for information purposes. (...) For example, the potential customer (...) will have to bring a used phone to participate in the event. This ensures that there is more awareness, and that the rhythm of circularity is also established. (...) because circularity is essentially this: no longer creating a transactional approach (I buy, you sell, etc., etc.) but the same phone passes from hand to hand. So, what do we want to do? We want, let's say, to break down this type of transactional market, to put phones into circulation, to expand the offer, that is, at a certain point we no longer work on phones, but also on services, in such a way that it becomes a habit, that is, the refurbished must become part of the habit of purchasing and using behavior" [*Alpha's Marketing Director, Interview 1 extract*].

For Beta: "We believe in the fundamental principles of sustainability, that in addition to making our profit we must distribute what we do throughout the territory, always respecting the environment. [...] if we collect waste [paper], it means that the value of the territory increases because employment increases and development increases. [For example,] 100,000 tons of papers that we collect means almost 300 more jobs, 80 million euros in value. [...] What does this mean? That the more paper we collect, the more money we save from municipalities and users, and the more we bring to them in the area. But this product must be processed in the area, and in turn it must bring employment. [...] What do we do for the territory? we, in our small way, if we earn enough, we can also give a lot to the territory; if we earn less we give less to the territory. I mean, we can give a little charity, we can help family homes, we can help the municipalities to separate waste collection, we can [develop projects together with the municipalities for the territory]". [*Beta's President and Founder, Interview 1 extract*].

Interviews results show that SO has been excellently interiorized in terms of environmental and social stewardship. In particular, Alpha pays great attention to the environmental side but considers having a direct responsibility in "breaking-down the transactional market" making the refurbished purchase an habit in the society. Beta is even more focused on the social dimension whilst caring for the environmental dimension at the same time. In fact, Beta argues that is fundamental to distribute part of the financial profit to the territory.

Humane Resource Orientation

HRO is qualified by four components: empathy, equity, enablement, and empowerment: (1) empathy is "the extent to which a company shares emotions and information with its employees"; (2) equity is "the extent to which a company treats individuals in a fair and equal manner"; (3) enablement is "the extent to which a company provides the environment where each individual employee is able to develop skills and knowledge, consisting of both skill and infrastructure"; and (4) empowerment is "the delegation of power and responsibility from higher levels of the organizational hierarchy to lower levels, especially in regard to an employee's ability to make decisions" (Kim et al., 2018, p. 21).

Empathy

For Alpha: "In the last three months we have started to make [...] a form of communication exploited on three levels. The first is team building. We actually have sessions within the various teams with me super partes and another person. And then we let the team members talk. So [everyone can] bring out all the gut perceptions so that we can discuss it. A free area in such a way as to have, let's say, a direct comparison with people who perhaps do not normally have the possibility of expressing themselves or in any case do not have an authoritative level. Then there is a level of communication between team leaders. Therefore, team leaders communicate and this ensures that there is more cohesion between the different functions. And finally there is company's communication to all its employees. So at the moment we are structuring ourselves and it is certainly an empathetic way of doing things, in the sense that we try to listen, we have yes, we have implemented this attitude". [*Alpha's Marketing Director, Interview 1 extract*].

For Beta: [In our company we took] guys [who] did an internship; they did two years of training. Today they are all permanent employees. Seeing these kids who you took from them at 20 years old who at 27-28 years old were able to buy a car, were able to get married, were able to start a family and have children... it becomes a very [satisfying] thing". [*Beta's President and Founder, Interview 1 extract*].

Equity

For Alpha: "Let's say, at the moment, when we are putting open positions online, we do it first and foremost, both in English and in Italian, precisely to give access to people who perhaps have difficulty with the Italian language but who still manage to get by. In this way we overcome the problem of language and at the same time also of ethnicity. [We specify] very clearly that we are open to all types of applications, so I also talk about the issue, let's say disability, the issue of the gender gap, [...] that is, [diversity gaps] are issues that we care about but clearly there is a background, I'm talking about the culture from which we come, which does not favor the entry of diversity within the company. [...] [In sum,] current state - future state: there is a difference [in term of equity that] [...] has not been addressed before, unfortunately, but for many reasons [...] but we are working on it". [*Alpha's Marketing Director, Interview 1 extract*].

Enablement

For Alpha: “The point is that on many tasks in which we are finding that there is perhaps a possible frustration - I am talking about years of work in the same sector and in the same job -, what is the only way to create perspective for the worker? That of differentiating the task. So, in 5 years from now the tester will not only be responsible for carrying out tests, but possibly we will have different figures always in the same sphere of action who will take care of, I don't know, coaching the new entrants, therefore carrying out boarding, etc.” [*Alpha's Marketing Director, Interview 1 extract*].

Empowerment

For Alpha: “Then, let's say, [the employee or worker is not authorized to] make decisions. But the idea that the employee can in his, in his [job routine] find the solutions to bring to management or to the executive, is something that has always been clear, always been, not only accepted, but welcome. So, let's say: on this I think there is clarity within the company. We are all in the same boat: so, obviously, finding a solution doesn't just mean bringing good to your own mill, bringing water to your own mill, but bringing water to everyone's mill. I think that there is no doubt about this: there is, there is a lot of openness on the part of the executives”. [*Alpha's Marketing Director, Interview 1 extract*].

For beta: “there is continuous participation of human resources. If someone makes an improvement, they do it and move on. [Executives do not block him]”. [*Beta's President and Founder, Interview 1 extract*].

Interviews data show that HEO has different levels of interiorization and also different understanding at least for some subdimensions. In fact, the four dimensions of empathy, equity, enablement and empowerment are clearly evident in Alpha only whilst for Beta there is evidence of empathy and empowerment only. Beta perfectly interpreted the concept of empathy, with its President so proud to share emotions, feelings, concerns, and goals of employees. On the other hand, Alpha shows a different level of empathy that seems to be just at initial stage, that is that of listening. Alpha has very clear the concept of equity in terms of equal treatment of all employees, recognizing that executives are still working on this aspect because for several reasons in the industry is still difficult to tackle the gender gap, diversity gap, etc. In addition, Alpha demonstrates not to fully grasp the theoretical conceptualization of enablement that is prevalently seen only as matter of job enlargement, remaining not well focused the issue of education and training in a global perspective. Related to empowerment for both the interviewed firms, executives are very open to leave some degree of freedom to their employees in taking autonomous decisions, but Alpha seems to be more restrictive than Beta.

Research limitations. *Whilst we make relevant contributions to the CE and HumEnt literature, we are aware that this study has also some limitations, mostly notably, the limited geographical scope and the number of organizations investigated.*

Theoretical and Managerial implications. *There are several theoretical and managerial implications deriving from this study. Firstly, this study finds that there are circular businesses presenting the HEO theoretical characteristics, thus adding empirical evidence to HumEnt literature and bridging circular business models studies to entrepreneurship investigations. Secondly, this study expands HumEnt theory recognizing that in humane entrepreneurial oriented firms the strategic posture is developed along the three lines of EO, SO, and HRO and demonstrating that is possible to find different levels of EO or SO or HRO. In sum, this study confirms the theoretical position of Parent et al. (2021) and Vesci et al. (2023) that only the presence of the three subdimension allows to classify the firm as a humane entrepreneurial oriented firm and that reality displays firms with a clear expression of only some of the subdimensions that compose HEO. Thirdly, findings suggest that in the CE field SO is clearly understood as both environmental and social, being aligned with previous study of Vesci et al. (2023). Fourthly, this study provides evidence of CE implementation thereby contributing to advance the CE literature, where most studies have been conceptual to date (Zils et al., 2024). Fifthly, as one of the cases stressed that a positive workplace climate and staff wellbeing are results of long-term action, managers and entrepreneurs must plan and organize training courses and team-building events, with the aim to reinforcing the familial feelings among the workforce. Finally, as HumEnt is not a simple task and it appears to be costly at least in the short run, institutions and governments should think to several forms of supporting firms that respect HumEnt principles.*

Originality of the paper. *This study contributes to the scant literature at the intersection between entrepreneurship and CE, and particularly to the nascent literature combining HumEnt with CE. In addition, this study analyzes firms that display an entrepreneurial strategic posture corresponding to a HumEnt approach contributing to the discussion on the HEO key characteristics in the CE field. Finally, the analysis shows that entrepreneurs' personal values and credos are strictly linked with HEO.*

Is Passion a Driver of Sustainable Entrepreneurship? An Autobiographic Analysis of Fashion Entrepreneurs

CECILIA PASQUINELLI¹ SERENA ROVAI² MATILDE MILANESI³ SIMONE GUERCINI⁴

Abstract

Sustainable entrepreneurship combines the identification and development of profitable opportunities with sustainability goals. Sustainability orientation is significantly influenced by the specificities of the entrepreneurial identity, which is a widely studied concept deserving dedicated research efforts to connect with sustainable entrepreneurship. Further investigation is required to enhance our understanding of the primary factors influencing the development of entrepreneurial identity in sustainable entrepreneurship, with passion being an aspect that has received minimal attention.

This work-in-progress paper expands knowledge on the sustainable entrepreneur's identity as a set of factors boosting and shaping sustainable entrepreneurship. Particularly, the focus is on a theoretical and empirical exploration of the phenomenon of passion throughout the entrepreneurial process oriented to sustainability. By adopting autobiography as a research approach and methodology, this study explores the entrepreneur's point of view on passion, its essence, formation and impact on the entrepreneur's decision-making and sustainable business venture. To what extent does passion contribute to sustainable entrepreneurship from the entrepreneur's point of view? How and to what extent does passion motivate and explain decision-making and actions according to the entrepreneur's reflective self-narration?

Preliminary results revealed that passion significantly emerged in the entrepreneurs' self-narration as a driver alongside their personal and professional growth path. Passion emerges as a training-driven and experience-driven phenomenon rather than an innate and natural propensity. Furthermore, the entrepreneur's perception and awareness of being in the condition to achieve concrete sustainability goals, based on skills, competencies and first-hand experience, seem to mediate the path from individual passion to a sustainable entrepreneurial venture.

Framing of the research. *Sustainable entrepreneurship frames the identification and development of profitable opportunities with sustainability goals. Sustainable entrepreneurship generates hybrid organisational forms combining "demand-based market logic with a need-based social logic" representing an organisation's social and environmental footprint (Stubbs, 2017: 332). Entrepreneurial activities producing solutions to social inequality and environmental degradation, rather than causing them, are considered a new field of research, still in its infancy due to the limited understanding of the nature of this phenomenon (Munoz and Cohen, 2018).*

Diverse research approaches emerged concerning sustainable entrepreneurship. Entrepreneurship theory perspectives have focused on intertwining sustainable development and the entrepreneurship process alongside the business idea's discovery, creation and exploitation (Terán-Yépez et al., 2020). Profiling and understanding the entrepreneur as an individual who can effectively frame economic, social and environmental dimensions into an organisation are at the core of this agenda (Young and Tilley, 2006). The entrepreneur's characteristics and attitudes have been under scrutiny as explanatory variables of sustainable entrepreneurship, such as knowledge and skills, motivations and intentions, values and attitudes, moral cognition, business orientation and entrepreneurial self-efficacy (i.e., belief in oneself capability to perform a task) (Munoz and Cohen, 2018). The sustainability orientation is significantly influenced by the specificities of the entrepreneur's identity, which, consequently, deserves dedicated research efforts in the sustainability domain. Beyond the cognitive mechanisms activated by life experiences, motivations and intentions emerged as the most critical factors of sustainable venturing, along with a "transformative mindset" pushing decision-making and actions (Munoz and Cohen, 2018).

Further investigation is required to enhance our understanding of the primary factors influencing the development of entrepreneurial identity in sustainable entrepreneurship, with passion being an aspect that has received limited attention (Mmbaga et al., 2020). Scholars have scrutinised how passion manifests as an entrepreneurial activity, whether through

conventional entrepreneurship or via unconventional paths within collective "tribes" (Biraghi et al., 2018; Cova and Guercini, 2016).

Passion has evolved into a pivotal component of identity, playing a crucial role in driving entrepreneurship presently and significantly influencing entrepreneurial intention (Fayolle and Linan, 2014), which is fundamental to entrepreneurial endeavours (Shah and Tripsas, 2007). In a study conducted in 2017, Bao et al. examined the relationship between entrepreneurial passion, opportunity recognition, and entrepreneurial behaviour, revealing that individuals with high enthusiasm for entrepreneurship were more likely to identify and launch new ventures (Bao et al., 2017). These studies draw upon Cardon et al.'s (2009) definition of entrepreneurial passion, which refers to the positive emotions experienced through engagement in entrepreneurial activities pertinent to the entrepreneur's self-identity. Entrepreneurial passion is understood as emerging when entrepreneurs feel strong positive emotions towards a particular entrepreneurial endeavour or "domain" they engage in, such as inventing, founding, and developing. They perceive this activity or "domain" as integral to their self-identity (Cardon et al., 2013). Besides the three activities of inventing, founding, and developing, entrepreneurial passion can be directed to other domains that represent the source of passion and what fuels it and drives entrepreneurial activity. Cardon et al. (2017) raise the question "Passion for what?" and identify six major sources of entrepreneurial passion: passion for growth, passion for people, passion for the product or service, passion for inventing, passion for competition, and passion for a social cause.

Following this line of reasoning, passion-driven entrepreneurship was analysed concerning different domains such as hobbies (Milanesi, 2018), cultural and artistic events (Pagano et al., 2018), hospitality (Pedeliento et al., 2018), and digital contexts as in the case of YouTube autopreneurs (Mardon et al., 2018). A literature review has evidenced that the current research is mainly focusing on the entrepreneurial passion perspective and evidencing the aspects related to domain passion or both the former and the latter perspectives' role in the entrepreneurial process. All the cases analysed do not seem to merely belong to the classic model of the entrepreneurial process (Reynolds & White, 1997) or the end-user entrepreneurial process (Shah & Tripsas, 2007). However, those company cases show a joint entrepreneurial process originated by domain and entrepreneurial passion, which has been limitedly analysed until now, according to the authors. Therefore, we wonder whether sustainability can be considered a domain of entrepreneurial passion and a driving force behind sustainable entrepreneurship.

Purpose of the paper. This paper expands knowledge on the sustainable entrepreneur's identity as a set of factors boosting and shaping sustainable entrepreneurship. Particularly, the focus is on a theoretical and empirical exploration of the phenomenon of passion throughout the entrepreneurial process oriented to sustainability. Through the autobiographic methodology, this research adopts the entrepreneur's point of view on passion, its essence, formation and impact on the entrepreneur's decision-making and sustainable business venture. How and to what extent does passion motivate and explain decision-making and actions according to the entrepreneur's reflective self-narration? To what extent does passion, as discussed in the extant literature, contribute to explaining sustainable entrepreneurship?

Methodology. From a methodological perspective, this research relies on the autobiography methodology to unveil the entrepreneur's self-concept, influencing critical decision-making (Fauchart and Gruber, 2011; Mmbaga et al., 2020). Even though significantly overlooked in business and organisational studies, autobiographies are retrospective self-representations (Hulsink and Rauch, 2021) with the potential to explore entrepreneurial identity.

Beyond being a tool for collecting and analysing data, autobiographies are a research strategy that substantiates the research point of view (Mmbaga et al., 2023), which corresponds to the first-person perspective of the investigated subject (the entrepreneur in our study). This method implies the subjective projection of identity work as an internal and reflective self-narration, giving insight into how the individual experiences the surrounding environment and constructs his/her identity (Mmbaga et al., 2023). The perspective of subjective self-narration may acquire further relevance in sustainable business, for the complexity of going beyond the purpose of economic profitability, potentially heightening the need for individual motivation and self-empowerment.

Storytelling and verbal representations are part of the narrator's entrepreneurial self-identity building and a sensemaking device to manifest identity (i.e. the entrepreneur, Mmbaga et al., 2020; Mmbaga et al., 2023) by giving meaning to actions and events in which the narrator is involved (Albert and Couture, 2013). Stories and life episodes verbally represent the entrepreneur's identity and legitimate the entrepreneur and his/her venture (Down and Warren, 2008).

The key difference with the biographical method concerns the internal "first-person account of thoughts, feelings and relationships" (Hulsink and Rauch, 2021, p. 914), contrasting with the multiple perspectives on the investigated subject given by biographies (Carradus et al., 2020). Autobiographies steer "internal self-reflection" through the reconstruction of one's life history, the critical moments of understanding and thoughts and cognition, emotions, and interactions with other actors in the form of temporal junctures, events and actions that have built the individual identity (Mmbaga et al., 2023). Unfolding processes, dynamic events and evolving individuals and organisations are under scrutiny through life history data (Hulsink and Rauch, 2021). Autobiographies allow insights into the organisation leaders' vocation and their challenges in translating their vocation into organisational practices (Corradus et al., 2020). Sense of self and sense of place (the organisational and the broader contextual and geographical environments) are the outcomes of this explorative technique.

Despite the social desirability bias to be considered when collecting and analysing data (particularly relevant when dealing with sustainability in both its social and environmental dimensions), autobiographies have been recently rediscovered to reach fruitful insight into individuals' feelings of suitability for being entrepreneurs, the challenges faced to translate their ideas into practices, and to dig knowledge into success and failure factors in the entrepreneurial venture

(Carradus et al., 2020). Besides, autobiographic narratives “represent not only an exercise in fact, but also one in which the writer chooses stories that can help create a positive narrative identity, perhaps to enhance self-image and reputation” (Mmbaga et al., 2023, p. 248).

Empirically, this study focuses on multiple case studies (Eisenhardt, 1989) to elaborate theory from autobiographies (Mmbaga et al., 2023). The object of analysis has been the entrepreneurial venture related to three Italian companies in the sustainable fashion industry (i.e., shoes, clothing, and textiles). Case Alpha, Case Beta and Case Gamma achieved a sustainable brand positioning according to the entrepreneurial choices over the business venture. The empirical analysis aims to explore the evolution of the entrepreneurial venture, drawing attention to the entrepreneur’s individual experience and the role of passion towards the definition of a sustainable business. The three cases were selected to fit the theoretical category (Eisenhardt, 1989) of firms with a sustainability vision whose stories and identities are tightly linked to the individual founder pursuing and personally committed to sustainability.

Case Alpha was founded in 2018 in Prato (Italy). The firm has 13 staff members and is a sustainable fashion brand of regenerated clothes, entirely locally produced. In Italy, it coordinates the collection of old clothes and the regeneration process into denim, cashmere, and cotton garments, and it is committed to strict control of the supply chain. It distributes its garments online and through resellers in Italy, Europe, and Canada. The firm’s turnover shifted from 650,000 Euro in 2020 to 3 million in 2022, drawing investors’ attention. Corporate sustainability is framed by using recycled and regenerated textiles, a pre-sale policy against overproduction and waste, reusable packaging, social responsibility and transparent business practices.

Case Beta was founded to use sustainable innovations to transform the footwear industry. With Zipshoe crowdfunding, the firm was established on Kickstarter in 2017 and was able to raise over \$1 million in pre-orders. Over the years, the startup has continued to innovate and stay true to its mission—that anything can be changed—. While analysing the fashion market, its founders realised that shoes, particularly sports shoes, had remained distant from sustainability concerns and practices even though young consumers were concerned about sustainability and their individual contribution to it. The founders stay true to their mission to modify the market and have established more than 70 partnerships with other luxury and fashion brands to share their R&D knowledge to further develop a sustainable change. In 202, it was certified as a B Corporation.

Case Gamma was founded in 1943, and is now one of the leading companies in the textile industrial district of Prato. The firm produces a wide range of undyed regenerated wool colours and luxury fabrics with different constructions, weavings and finishings, all made with recycled wool. The firm pursues growth and expansion objectives based on the values of sustainability, a zero-waste system, sustainable design, and traceability. The firm’s turnover in 2022 approached 100 million euros, over 90% of which came from foreign markets.

This study collected data through primary and secondary sources (i.e., websites and social media), including texts and videos reporting the entrepreneurs’ first-person perspective and representation of the self throughout their entrepreneurial venture. In-depth interviews with the entrepreneurs were carried out. The interview process focused on the process of becoming an entrepreneur and the subsequent evolutions: a first round of questions followed an unstructured interview scheme to reduce the researcher’s intrusiveness (Meyer, 2020), while a second round of questions followed a semi-structured scheme further stimulating the interviewee to elicit events and actions remarking life history phases, critical moments and the interviewee’s cognitive and emotional engagement, interactions with other actors. Different rounds of interviewing are sought to overcome the issues of time limitation and limited reflection through an intrusive data collection technique (Mmbaga et al., 2023). Different interview rounds may consolidate the interviewer-interviewee relationship, enabling the interviewees’ “intimate account of cognition, emotions and relationships that are central to identity formation” (Mmbaga et al., 2023, p. 248). The secondary data sources provided additional self-reflection traces, helping mitigate the limitations of the interviewing process in the autobiographical method.

All the collected textual data were analysed through qualitative content analysis (Krippendorff, 2004), holistically deriving insights and meanings from the text and reducing the decontextualization of meaning inherent to quantitative content analysis. A systemic coding process was undertaken by combining inductive and deductive approaches (Cho and Lee, 2014). Texts (i.e., website texts and video transcripts recording the entrepreneurs’ voice, and interview transcripts) were, first, analysed without adopting initial codes, letting codes emerge from the text; subsequently, a deductive approach to coding ensured the systemic analysis of text according to the key dimensions that the auto-biography allows eliciting according to extant literature (e.g., life history phases, critical moments, interactions). A flexible pattern matching (Bouncken et al., 2021) develops categories and identifies relationships framing passion and its role in the entrepreneur’s personal and professional path.

Results. This work-in-progress study has produced some preliminary results.

In both Alfa, Beta and Gamma cases, individual passion emerged as not just an innate and natural propensity of the individual consumer, who then becomes an entrepreneur. The entrepreneurial venture in sustainability results from an articulated combination of unconventional factors. As evidenced, previous streams of research have contributed to the debate on the process that leads to “unconventional” forms of entrepreneurship (Cova & Guercini, 2018) and specifically from passion to business (Chen et al., 2015; Biraghi et al., 2018; Cova & Guercini, 2016; Guercini & Ceccarelli, 2020; Cardon et al., 2017). The emerging autobiographical narratives of the sustainable entrepreneur raise the following three points which will inform subsequent analysis.

Firstly, the entrepreneur's passion widely emerged in narrating the individual path of personal and professional growth. Their passion for sustainability has been shown to impact on how they conceive their role in the market and the company's positioning as "non-competitive", as firms are active in implementing and sharing sustainability practices (Lawrence et al., 2006). Accordingly, in their narratives about their professional growth associated with the creation and development of their venture, the entrepreneurs have recalled the significance of the role of "activators" of sustainable business networks that the firms have, overcoming the competition logics, business network conclusions and boosting cooperative schemes through connections (Halinen et al., 1999), since the early phases of development.

Secondly, in the sustainable entrepreneurs' self-representation, the narrated passion is a training-driven and experience-driven phenomenon. In the process of translating and transforming passion into a business (Biraghi et al., 2018; Cova & Guercini, 2016), the entrepreneurs' self-account leaves behind the concept of passion as an innate and natural propensity. Sustainable entrepreneurial venturing combines a training-driven and an experience-driven passion for sustainable fashion. About training-driven passion, formal education, as an opportunity to learn skills and competencies through university degrees (fashion learning programs), and on-the-job training in the early phase of professional development framed the entrepreneurs' passion. The second component (i.e. experience-driven passion) concerns the entrepreneurs' immersion in territorial contexts where the environmental and social issues were highly visible and a lived experience (i.e., travel and work experience in emerging countries where they had a first-hand experience of extreme consequences of environmental pollution and social inequality).

Thirdly, the entrepreneur's perception and awareness of being in the condition to achieve concrete goals seems to mediate the path from passion to the entrepreneurial venture. This emerging state of mind resounds with entrepreneurial self-efficacy (Chen et al., 1998), whose connection with passion was discussed by Cardon and Kirk (2013), framing entrepreneurial persistence. Our study's results shift the focus to the enterprise start-up phase, providing preliminary evidence of the entrepreneurs' understanding of skills and competencies, combined with their lived experience, as boosters of consciousness, sense of responsibility, and intimate mechanisms connoting passion as a driver of sustainable entrepreneurship. From the entrepreneurs' self-portrait, skills, competencies and first-hand experiences compose the entrepreneur's background, substantiating cognition and feeling of being able to find concrete, valuable solutions and make an impact.

Research limitations. This is a work-in-progress paper that, relying on an initial empirical study, currently presents various limitations. In autobiography methodology, various issues should be considered, including the researchers' positionality and the relation with the object of analysis, especially concerning interviews, and the social desirability bias. Nevertheless, the constructivist nature of the adopted methodology recalls our attention to the knowledge built by human representation resulting from context- and goal-dependent sensemaking (Albert and Couture, 2013).

The analysis mainly focused on verbal representation and texts, with limited (and non-systematic) analysis of visual data that especially online sources may provide (e.g., social media accounts).

Managerial implications. Significant implications concern the modalities to nurture sustainable entrepreneurship, which is fundamental to addressing several contemporary societal challenges. The results of this study suggest the relevance of the role of "activator" in the field, educational programs, and exposure to lived experiences in framing passion and its capacity to trigger entrepreneurial development. Education organisations and those in charge of boosting and accelerating sustainable entrepreneurship should consider the results emerging from the proposed analytical perspective, as well as NGOs and consulting companies focusing on sustainability that could positively impact a change in the business.

Originality of the paper. This study is built at the intersection of two significant gaps in the literature. First, understanding passion as a driver of sustainable entrepreneurship potentially adds to the existing conceptualization and discussion of entrepreneurial passion. Second, it expands entrepreneurship studies by adopting autobiographies, a research approach and methodology that has remained largely underexploited.

Social Innovation: a literature review mapping intellectual structure of the field

LORENA GONZALEZ¹ ELENA CASPRINI²

Abstract

This article is based on a systematic review of literature on social innovation with the purpose of understanding and defining the current intellectual structure of this research area. This study aims to serve as a starting point for advancing theory on social innovation. Previous literature has shown that as a field of study is highly underdeveloped while at the same time it is very fragmented. This has given rise to the need to find a clear visualization of what are the most relevant topics related to social innovation. We used a systematic review of the literature using bibliometric techniques for analyzing 132 peer-reviewed articles published in journals ranked as 4 and 4 by the Chartered Association of Business Schools 2021. Using a bibliographic coupling analysis, we identified five clusters. Our analysis has implications for researchers looking to advance research on social innovation as well as for firms looking to positively impact society.*

Key words: *social innovation; social entrepreneurship; social entrepreneur; social value*

Framing of the research. *Social Innovation is a topic highly debated in academia. Even though some of the first studies in this field were published in the early 1990's, it is a topic that has gained relevance in the last decades. Despite of the high interest in furthering knowledge on this field, there are also high levels of heterogeneity in terms of disciplines and theoretical approaches exploring this topic. Management scholarship is no exception to this and studies on social innovation have been developed from diverse perspectives such digitalization and other types of innovation (Fosso Wamba et al., 2021; Mariani et al., 2023), collaboration among different sectors (Lenz and Shier, 2021), and corporate social innovation (Dionisio and de Vargas, 2020). However, among these perspectives, there is a great body of literature studying social innovation as part of, and in connection with, research on social entrepreneurship.*

Lortie and Cox (2018) found that social innovation is one of the most related areas concerning studies of social entrepreneurship along with other topics such as corporate social responsibility (CSR), bottom-of-pyramid (BOP), Non-profit management, and impact investment. Based on their findings, these authors called for further research in understanding differences in the antecedents of social innovation and social entrepreneurship and whether social innovations produced by social enterprises differ from social innovations produced by traditional forms of organizations.

On the other hand, Phillips et al. (2015) also build on theory on social entrepreneurship in order to understand the relationship between social entrepreneurship and social innovation, as well as identifying frameworks that bring together these two topics. They found that social innovations stem from the interaction among different actors within the social system and developed through collective learning. Multisector collaboration and partnerships are indeed, one of the common grounds among studies on social innovation despite of the existing heterogeneity and lack of consensus in what is social innovation.

Another line of research growing in recent years is that of digital technologies as means that could be used for achieving social impact. Within this line of studies, we found that Dionisio et al., (2023) examined the evolution of the concept of digital social innovation and whether it connects (and in which way) with the sustainable development goals of the United Nations.

Moreover, in addition to showing a vast number of studies examining theories and frameworks on traditional entrepreneurship and innovation and how they relate to social innovation and social entrepreneurship, research on social innovation is concentrated for most part in qualitative methods among which there is prevalence for empirical studies, (Desa and Koch, 2014; Ulfah and Dhewanto, 2015) which can be explained by the fact that it is a stream of research still in early stages.

Purpose of the paper. *Given the great fragmentation faced by this field it is important to understand and clearly define the current intellectual structure of this research area to advance theory on this topic. So far, research on social innovation has grown in terms of number of contributions, with many of them reviewing current literature. However, there is a lack of depth in the development of the different sub-fields of study stemming from this topic. Considering this idea, the aim of this paper is to analyze the main contributions to the literature on social innovation by identifying the*

¹ e-mail: gonzalezfumerolorena@gmail.com

² University of Siena
e-mail: elena.casprini@unisi.it

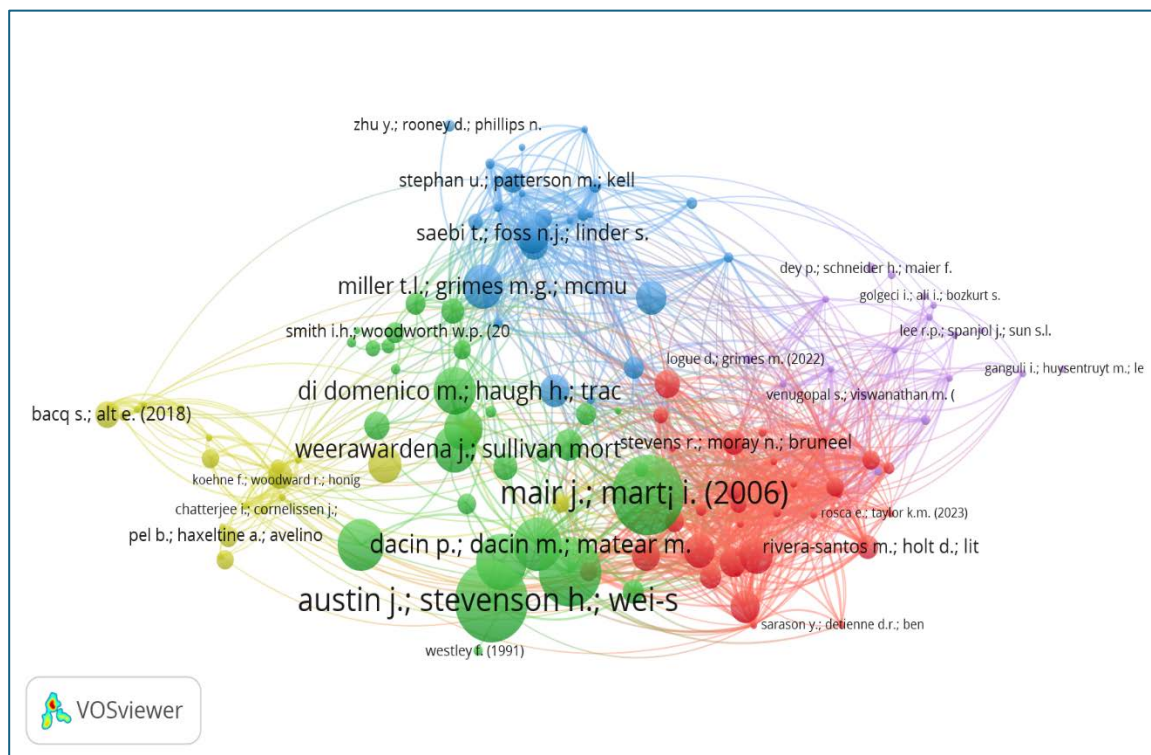

main general areas in which the current studies have concentrated as well as key research gaps that could guide the path for a larger study on Social Innovation, thus serving as a foundation for a deeper theoretical development.

Methodology. To describe the current structure of the literature on social innovation, we conducted a first exploration of current research on social innovation using the Scopus data base to find articles based on previous reviews on social innovation. We used the terms “social Innovation” AND “review” to search within title, abstract, and keywords to search articles within the subject area of Business, Management and Accounting that were published in English. This initial search resulted in 114 articles from which a sample of 27 documents was extracted. These articles were examined to identify the most common keywords used by other authors to search for studies on social innovation. Furthermore, we performed a systematic review on these 27 documents in order to better positioning our paper.

Once we completed the identification of keywords, we built a new search string in Scopus with the terms "social innovat*" OR "creat* shar* value*" OR "csi" OR "social entrepr*" OR "social enterpr*" OR "purpose* organi*ation*" OR "hybrid organi*ation*". This was the best combination of keywords to be used for searching on the database within title, abstract and keywords. In addition, to these search terms we considered all articles published up to December 2023 (included), published in English within Business, Management, and Accounting. The search displayed a total of 9181 articles which we ranked using the Chartered Association of Business Schools ranking and selected those articles ranked in Journals classified as 4 and 4* (top journals). Doing this, we extracted 1271 articles. After carefully screening the abstracts, we were left with a final sample of 132 articles.

To analyze the data, we conducted a bibliometric analysis using bibliographic coupling. Bibliometric analysis is considered a rigorous method for exploring and analyzing large volumes of scientific data while bibliographic coupling provides a representation of the current structure of a research field (Casprini et al., 2020; Donthu et al., 2021). Using VosViewer software, we mapped the data selected in our sample which allowed us to identify 5 different clusters as illustrated in figure 1.

Figure 1

Results. From a total of 132 articles considered for the analysis, 126 were part of one of the five clusters identified. Consequently, the remaining 6 articles did not have any connection with other documents. Therefore, they were excluded from the bibliographic coupling analysis. Based on the total number of citations of each cluster, the analysis present cluster 1 as the most influential one with 13371 citations.

Cluster 1

The first cluster is the largest cluster with 33 documents. This network is highly dominated by research on the initial stages of entrepreneurial activities and the intersection between strategy and organization theory and social entrepreneurship theory. Articles covering these topics represent 60% of the documents in this network. In addition, four documents focused on the potential of Tourism Social Entrepreneurship for the transformation of communities.

Within this cluster, there are three documents offering insightful theory with the potential to develop grounds for further studies, two of them are based on reviews of previous literature. The first one is the work of Stevens et al., (2015) who identified dimensions for delineating social and economic missions. These authors built on theoretical constructs to propose different dimensions (measures to capture value, organizational identity, and attention to social and economic goals) for understanding the relationship and navigating tensions between social and economic missions of social enterprises.

Another relevant paper in this cluster is Choi and Majumdar, (2014). In their work, they propose to approach research on social entrepreneurship defined as a conglomerate of more than one sub-concept (social value creation, the social entrepreneur, the social entrepreneurship organization, market orientation and social innovation).

In addition to the two articles mentioned above, within this cluster is the work by Rawhouser et al. (2019). Emerging in the second half of the period covered by this cluster, this study examines previous research on social impact. In this review of the literature, the authors find a high level of heterogeneity among the different studies that had been conducted with the aim to establish a definition of this concept. As a result, they propose a typology of four different approaches stemming from two dimensions to conceptualize social impact. The two dimensions are: according to the social impact process and according to the generatability of the application.

Cluster 2

This network covers the largest period from 1991 until 2020, with 29 documents with the most part concentrated on issues related to social entrepreneurship education and learning with eight documents, and another important group of documents examining different aspects of social entrepreneurship. The rest of the articles in this cluster examine topics related to social innovation, social entrepreneur, and the creation of social enterprises. This cluster represents approximately 59% of the total citations among the five clusters, which puts it forward as the most influential network in this analysis.

As part of this network, the work by Dacin et al. (2010) presents the highest degree of centrality. This article proposes a different approach to social entrepreneurship studies concluding that the greatest opportunities for researchers interested in this field are in studying this concept through the lens of a theories and frameworks related to regular entrepreneurship applied to the social context.

Moreover, another document that stands out in this network is the one by Dacin et al., (2011) diving into the promise of social entrepreneurship as a new domain of study and propose avenues for future research. Among opportunities to further studies on social entrepreneurship, by examining previous contributions to the conceptualization of social entrepreneurship they propose that to advance theory on this topic it could be useful to focus on outcomes and contexts. In doing so, studies could offer meaningful ways to understand this concept from a theoretical and practical perspective.

Finally, one third article in this network that proposes relevant theoretical grounds for the development of further research is the one by Zahra et al., (2009). This study reviews the concept of social entrepreneur proposing three different typologies that determine the way in which social entrepreneurs identify opportunities, determine their impact, and put together the resources needed to pursue them. Furthermore, they highlight the emergence of ethical issues stemming from linking economic thinking with the generation of social wealth, understood as a metric to measure how social entrepreneurship contributes to the maximization of total wealth.

Cluster 3

This group of articles shows the highest density of connections, and it comprises the same period as cluster 1. This cluster shares the highest density of connections, where the work by Miller et al., (2012) results as the one with the highest degree of centrality. This article discusses the role of compassion in encouraging the creation of social ventures, building on theory about the relationship between social entrepreneurship and compassion focusing on affective and cognitive mechanisms and they offer contribution not only for the social entrepreneurship filed but also for entrepreneurship research.

Vedula et al. (2019) discussed the concept of entrepreneurship for the public good by reviewing literature on social and environmental entrepreneurship to dive into the evolution (with converging paths) of these two concepts as well as identifying specific areas of collaboration between them. They propose how the two streams can be integrated to understand how entrepreneurship as a field of study can contribute to the public good.

Finally, Lazzarini (2020) proposed a framework for explaining how three forms of organization (public bureaucracy, public-private partnership, and social enterprises) support social value creation. This document offers insight on measurement of social impact which is a highly underexplored topic within social entrepreneurship research.

On the other hand, Saebi et al., (2019) offer an analysis relevant for advancing studies on social entrepreneurship. By reviewing literature on social entrepreneurship, they propose that theory on social entrepreneurship can benefit from using a multilevel analysis (at the individual, organizational and institutional level) approaching social entrepreneurship based on two dimensions, one concerning whether the social value is created by or for the beneficiaries, and the second one according to the level of integration between social and commercial activities.

Cluster 4

Cluster 4 unfolds within the period of 2012 to 2023. Topics examined by the articles in this network address different perspectives on innovation research connecting different theories, approaches, and concepts with their ability to impact society. This cluster is for most part concentrated in articles touching on different aspects of social entrepreneurship such as prosocial power and pro social perspectives, as well as documents examining the role of human capital and communities in the success and development of social entrepreneurial initiatives.

Central in this cluster we find the work by Koehne et al., (2022) who examined the role of the transnational social entrepreneur and their ability to impact, whether positive or negatively, the lives of disadvantaged communities. This article stands as the one with the highest number of shared references in relationship with the rest of the documents in this group. Moreover, the most influential article within this cluster is the one published by van der Have and Rubalcaba, (2016) addressing the evolution, content, and scope of Social Innovation across different disciplines as a nascent field of research. The authors highlight importance of multi and intradisciplinary approaches in understanding and defining Social Innovation, emphasizing that despite the high levels of fragmentation of this field, it should be studied taking into consideration two main core conceptual elements. The first one, that social innovation implies change in social relations, systems, and structures, and that these change aims to address the need to solve an important social problem. This is one of the first systematic reviews using bibliographic data to describe the intellectual structure of this research field.

In addition, from the 22 documents included in this network, Estrin et al., (2016) highlighted the importance of human capital in entering entrepreneurship by extending human capital theory to social entrepreneurship. In contrast with previous studies addressing this area, they highlight the relevance of “taking into account ability and skills to understand who is more likely to become an entrepreneur” (p.465) (add page number).

Bacq and Aguilera, (2022) on the other hand, address the role of community engagement in generating social impact. In their study, these authors identified a continuum of community roles ranging from passive beneficiaries to highly active entrepreneurial social change agents, and a set of different typologies that describe communities.

Cluster 5

This cluster is the smallest one in terms of number of documents and lowest number of total citations with 301, however it is the third one in terms of density of connections, covering a period of eight years of research. This group of articles is concentrated in the field of strategy, organization, and innovation. Unlike most of the clusters described above, in which there is an evident dominance of research focused on social entrepreneurship, traditional entrepreneurship and innovation, this network includes an important number of articles specifically addressing the topic of social innovation (Fu et al., 2023; Ghauri et al., 2023; Kruse et al., 2019; Marcy, 2015; Steinfield and Holt, 2019; Vassallo et al., 2019; Venugopal and Viswanathan, 2019; Viswanathan and Sreekumar, 2019). In addition, this cluster is dominated by articles addressing contexts of grand challenges, bottom of the pyramid and bottom-up approaches to social innovation as well as complex humanitarian problems.

Within this network, the article by Venugopal and Viswanathan (2019) is the one with the highest degree of centrality. Through empirical analysis of a sample of social enterprises operating in different country contexts, they have developed a process of “facilitated institutional work” to implement social innovation. This model is characterized by the participation of local communities in driving institutional changes to facilitate the implementation of social innovation. In addition, the most influential paper on this network (the one with the highest number of citations) is the work of Logue and Grimes (2022) linking the creation of digital platforms for enabling social innovation and institutional theory.

Discussion

As discussed in the literature review section of this paper, the high level of fragmentation among studies concerning social innovation is evident. It is also evident the fact that social innovation on its own as a line of research is highly under explored and lacks depth and structure. Furthermore, most of the efforts of many scholars looking to explore different paths to social transformation and social impact is focused on the study of social entrepreneurship linking it to a wide spectrum of theories where in most cases are theoretic foundations already established in the study of traditional entrepreneurship.

Little attention has been paid to the potential of social entrepreneurship and social innovation in the context of education. Evidence of this is the distribution of the articles in cluster two, where even though the proportion of articles within this network is even the most cited documents in the cluster continue to fall within the line of social entrepreneurship as an extension of traditional entrepreneurship. In line with this, one of the main findings of (Batista and Helal, 2023) is the fact that studies examining the relationship between social innovation and education show a time gap of 30 years without published research addressing this connection (1984 and 2015). This represents a potential for developing future lines of research on education related to social entrepreneurship and innovation, and the role of educational institutions in promoting social entrepreneurship and social innovation. Approaching research from this perspective may also be relevant for the achievement of sustainable development as it directly impacts the social development goals.

Moreover, when planning to advance theory on social innovation and social entrepreneurship it can be useful to follow the propositions by van der Have and Rubalcaba, (2016) suggesting that regardless of the discipline, any definition of social innovation should take into account that it implies changes in relationships, systems and structures in order to address to solve an important social issue. While it has been suggested that lack of focus in one aspect of social innovation has constrained the possibilities to build deep theoretic foundations for this field, it is also to acknowledge that the

complexity of this phenomenon requires insights from multiple disciplines beyond management, such as psychology, sociology, and education. However, from a management perspective, one possibility to address social innovation research is to consider as a starting point the suggestion by Choi and Majumdar, (2014) where social innovation is part of a cluster of different concepts that define social entrepreneurship.

As a final consideration of this analysis is to highlight that it is necessary for scholars in this area to start digging deeper rather than growing wider to set strong roots for the development of theory in this field. While there is no doubt of the rigor and validity of previous research, it is necessary to start building grounds for further studies using mixed and quantitative methodologies to obtain results that can be generalized.

In summary, the aim of this review was to analyze the intellectual structure of social innovation and identify the most relevant lines of research connected to this concept. In doing so, analyzed bibliometric data using VosViewer to conduct a bibliographic coupling analysis. From the analysis we obtained five clusters. Overall, research on social innovation is highly overlapped with research on social entrepreneurship due to the very thin boundary between these two concepts. In the results, the second cluster stands out for having the highest number of citations compared to the total number of citations in the other clusters. One key finding of this group of articles is that articles on social entrepreneurship overshadow the potential of studying social innovation and social entrepreneurship in the context of education. Furthermore, the discussion of this analysis also brought attention to the need for expanding knowledge on social innovation as a definition within a group of sub concepts of social entrepreneurship.

Research limitations. Among the limitations of these study, it is to note the fact that the selection of the data was restricted to top ranking journals classified as 4 and 4* by the Chartered Association of Business Schools. Even though this inclusion criterion is rigorous in ensuring that the publications selected offer important advancements in their fields, it would be interesting to widen the scope of coverage of the data to include articles published in journals with different ranking levels. In addition to expanding the range of articles to be analyzed, the bibliographic coupling analysis could be complemented with a co-citation analysis to identify not only how the field of social innovation is structured but also to identify the knowledge bases of this topic.

Managerial implications. Our study has implications for the advancement of theory on social innovation that can benefit organizations from different perspectives. New theory on social innovation can have a positive impact on innovation processes within firms looking to achieve social objectives. Moreover, by enhancing collaborations with relevant stakeholders. And finally, it can be useful for strategic decision-making processes while guiding a path to a sustainable business model.

Originality of the paper. Our study is one of the first reviews on social innovation using bibliographic coupling to map the current intellectual structure of this domain. Even though previous reviews of social innovation literature have used bibliometric analysis we found few studies using bibliographic coupling to proxy of the state of the art of their focal domain, however these studies were not focused on social innovation (Mariani et al., 2023).

Open Innovation Ecosystems support and development: a case-study

GIORGIO DI FIORE¹

Abstract

Open Innovation Ecosystems are regarded as a subset of Innovation Ecosystems in which all involved actors' primary scope is Open Innovation, and most of the activities carried out by the ecosystem participants are defined as Open Innovation activities. Yet, particular gaps in the literature limit our understanding of how Open Innovation activities can support the development of an ecosystem, especially those activities employed by participants that engage with a large firm or with the ecosystem orchestrator. For this reason, this study aims at exploring the role of ecosystem actors in supporting the development of an Open Innovation Ecosystem. Through an in-depth longitudinal case-study of "ORA! – Outpost Ravenna for Energy Transition", the present study aims to fill this gap by investigating the Open Innovation activity of the ecosystem members that collaborate with Eni, the leading Italian multinational energy company operating in the oil and gas sector, in developing its Open Innovation Ecosystem support initiative.

At the time of writing the study is still in progress.

Key words: *open innovation; ecosystem; process; ecosystem development; support*

Framing of the research. *The concept of Innovation Ecosystem (IE) has gained popularity in the last decades and quickly become a prominent research topic in cross-disciplinary academic literature (Oh et al., 2016; Granstrand and Holgersson, 2020; Alam et al., 2022). IEs originate both from the innovation system (IS) concept, which portrays a set of intertwined components and relations that influence the creation and utilization of innovation and innovative performance (Granstrand and Holgersson, 2020), and from the ecosystem concept, which comes from the science of ecology and represents the flow of material and energy (Shaw and Allen, 2018).*

In response to a call for more conceptual rigor, Granstrand and Holgersson (2020) reviewed the received definitions of IE and related concepts and proposed a new comprehensive definition. Their review suggests that the concept of IE places emphasis on collaboration between actors, value creation and competition. Accordingly, they conceptualize an IE as "the evolving set of actors, activities, and artifacts, and the institutions and relations, including complementary and substitute relations, that are important for the innovative performance of an actor or a population of actors" (Granstrand and Holgersson, 2020, p.3). The important factor that allows to distinguish the IE concept from the IS one, is indeed the collaboration between actors in an ecosystem and their competitive behavior; moreover, ISs are largely based on physical and geographical boundaries, while IEs allow for cross-sectoral and cross-regional exploration of innovation activities (Carlsson et al., 2002; Lundvall, 2007; Grandstrand and Holgersson, 2020; Pushpanathan and Elmquist, 2022).

In the context of IEs, existing research has devoted particular attention to the collaborative arrangements between the networks of actors who share knowledge with the aim of developing innovations (Bacon et al., 2019). Accordingly, innovation activities have seldom been found in isolation; rather, they are part of collaborative changes that happen around a firm's environment and that require collaborative innovation which eventually incorporates the firm into an interdependent IE (Xie and Wang, 2020).

As Alam et al. (2022a) underline, innovation literature has often showed how successful innovations need knowledge, resources and capabilities that come from external sources, and one of the most suitable strategies to meet this challenge is to adopt Open Innovation (OI). OI is defined by Henry Chesbrough (2003; 2012) as an emergent model of innovation by which firms rely on knowledge that arises outside the company's boundaries, and as a process that allows the distribution of innovation through knowledge flows across organizational boundaries. An extensive body of research has investigated the benefits of OI implementation from strategic, managerial, and organizational perspectives (Chesbrough et al., 2006; Enkel et al., 2009; Spender et al., 2017). The benefits of adopting OI include access to external knowledge, lower costs of technology development and improvement, quicker time to market, and higher quality products (Wallin and von Krogh, 2010). The OI process consists of three phases (definition, design, implementation) and involves the identification and the use of resources and ideas that rely

¹ Cattolica del Sacro Cuore University
e-mail: giorgio.difiore@unicatt.it

outside of the firm. It is a process of vision of innovation and organizational capacity to put innovation into practice (Grönlund et al., 2010; Lee and Jung, 2021). An ecosystem consists of a dynamic and interactive connection between the actors, featured by innovative thinking and focused on the creation and diffusion of knowledge. Consequently, firms that engage in a specific ecosystem co-develop and co-create with the actors involved in the same ecosystem and in other ecosystems.

In OI studies, the ecosystem perspective is particularly relevant, since it shifts the focus of analysis from a firm-centric approach to OI, to an approach focused on how the innovation process involves cross-boundaries interactions between actors; therefore, OI studies now adopt the IE concept to explore how a focal firm develops relations with external and interdependent partners (Wikhamn and Styre, 2022). Accordingly, numerous studies now adopt the concept of Open Innovation Ecosystem, which is intended as an IE in which the primary goal of the stakeholders is OI, where a substantial number of the supported activities are OI activities, and in which the primary goal of partner firms is OI (León, 2013; Xie and Wang, 2020; Alam et al., 2022a). The most relevant contributions about OI ecosystems, despite providing a definition, are scattered, and build on diverse theoretical frameworks. For instance, West and Wood (2008) explored the creation and evolution of an OI ecosystem with a longitudinal case study of a mobile operating system developer, and they developed their theoretical framework on value networks, business ecosystems, and their role in OI strategies. Fasnacht (2018), with a focus on value delivery in financial services asserts that, with open interactions of all members and hyperconnectivity, the system becomes an entity full of value; therefore, the collaborative approach to OI allows members to become flexible and agile enough to adopt the proper business model to engage in an ecosystem. In the context of product innovation, Xie and Wang (2020) assert that the modes through which actors engage and interact within OI ecosystems need to be explored; based on grounded theory, they found six innovation ecosystem modes (i.e., firm-university-institute cooperation, inter-firm cooperation, firm-intermediary cooperation, firm-user cooperation, asset divestiture, and technology transfer) and explored how their combination support product innovation. In a subsequent study, the authors define OI ecosystem as “combinations of innovation niches that are filled by linked firms” (Xie and Wang, 2021, p. 1); they build their theoretical framework on innovation niches and ambidextrous innovation to develop and test a conceptual framework to understand the internal mechanisms and contextual conditions in the relationship between a firm’s innovation niche and its exploratory and exploitative innovation (Xie and Wang, 2021). Alam et al. (2022b) use grounded theory method to understand the process by which firms open (i.e., adopt OI practices) to shift from a “closed” ecosystem, to an OI ecosystem, and developed a process of inter-firm openness with implications for the product innovation management.

Purpose of the paper. As previously mentioned, in an OI ecosystem the activities carried out by the actors involved are OI practices, and the primary goal of partner firms and stakeholders is to realize OI. Nevertheless, despite the increasing popularity of the concept, the numerous studies that explore OI ecosystems still lack in providing a comprehensive understanding of the role of OI in supporting the creation and the development of an OI ecosystem. Rather, their focus of analysis is on the main actor of an ecosystem (i.e., large firm or incumbent). Randhawa et al. (2021), for instance, explored the adoption of an “open” business model by a large firm in the medical sector to overcome cognitive constraints and create and capture value with collaborations with multiple stakeholders. Robaczewska et al. (2019) explored the adoption of OI strategies of a multinational firm in the pharmaceutical sector to understand the benefits of OI adoption in its regionally embedded IE. Gionfriddo and Piccaluga (2023) adopted the “Creating Share Value” dynamics lenses to investigate the OI adoption of a big player in the renewable energy sector to achieve social and environmental benefits against climate change.

The main research challenge is to select a setting that could help gaining a better understanding of OI support to ecosystem development considering as unit of analysis all actors involved in an ecosystem, and their contribution to the development of an OI ecosystem. Drawing on the OI paradigm and the resource-based view (RBV), this study aims to understand how the OI activities carried out by the actors in an ecosystem can support the development of it. The resource-based theory defines an organization as a bundle of physical, human capital, and organizational capital resources that must be valuable, rare, and imperfectly inimitable in order to hold the potential of a sustained competitive advantage (Barney, 1991). OI is “the use of purposive inflows and outflows of knowledge to accelerate internal innovation, and expand the market for external use of innovation, respectively” (Chesbrough, 2006, p.1); consequently, the main purpose of adopting OI is to access resources and knowledge. For this reason, the RBV is critical to understanding OI ecosystems (Alam et al., 2022a).

This study aims at developing a process model that explains (1) how actors are involved, collaborate in, and support the development of an OI ecosystem through the implementation of OI practices, and (2) how the ecosystem consequently evolves.

Methodology. To address the research objective, a process approach (Langley, 1999) and a single, in-depth case study (Yin, 2014) have been adopted, for two reasons. First, a “critical case” that is key to investigate the phenomenon illustrated above was selected (Yin, 2014). Second, the research objective requires a longitudinal study (Yin, 2014), which would allow to analyze the evolving nature of the relationships between the actors within the ecosystem. A process approach (Langley, 1999) holds particular significance for the purposes of this study since it allows to elaborate precisely throughout the evolution of the case. Additionally, process data is focused on the evolution over time of something, and the motivations behind its development; accordingly, it mainly consists of narratives about an event with particular attention to the steps, activities and choices that led to it (Langley, 1999).

Following purposeful sampling (Patton, 2014), “ORA! Outpost Ravenna for Energy Transition” is selected as a critical case since it is strategically aligned with the inquiry’s purpose. It is not uncommon in the OI field of research to

adopt purposeful sampling approaches to elaborate theory from information-rich case studies where authors have the possibility to conduct multiple rounds of interviews with a broad spectrum of key informants (Chesbrough et al., 2014; Robaczewska et al., 2019; Randhawa et al., 2021; Wikhamn and Styhre, 2023; Zhao and Yi, 2023; Gionfriddo and Piccaluga, 2023). “ORA!” is a new open innovation ecosystem support initiative to boost innovation within a traditional oil & gas industrial cluster with Eni² as the focal firm. Initiated by Eni and the Municipality of Ravenna in late 2022 with the technical partnership of Mind the Bridge³, it is meant to foster innovation and accelerate the transition towards sustainable energy solutions.

“ORA!” is a significant case for the purposes of this study and constitutes one of the most particular archetypes of OI ecosystem, for many reasons. On the one hand, Eni puts consistent effort in embracing OI. It is among the “100 TOP Corporate Startup Star” and won the “Open Innovation Challengers” prize promoted by the International Chamber of Commerce and Mind the Bridge (Mind the Bridge, 2023). On the other hand, as mentioned, “ORA!” was born from a joint initiative between Eni and the Municipality of Ravenna with a strong international vocation, focusing on technologies for the blue and green economy and, most importantly, with the aim of supporting local business transition and openness. It represents a singular way to allow local Small-to-Medium Enterprises (SMEs) to embark on OI activities. Additionally, the relevance of “ORA!” as a case study arises also from the variety of actors involved that interact and collaborate within the ecosystem. First, the large corporate, Eni, that runs hubs in different Italian regions and fosters entrepreneurship and entrepreneurial culture through “Joule”, the Eni’s school for entrepreneurship. It supports the growth of innovative startups with a strong impact on decarbonization, sustainability, and circular economy through incubation, acceleration, and pilot programs within its network. Second, the Municipality of Ravenna which is actively participating in the development of the ecosystem. Third, local SMEs working in the supply chain of Eni that are trained on methodologies and best practices related to OI, participate in networking activities and working groups and get support in identifying innovation needs and innovative solutions to solve them. Fourth, the University of Bologna (plus other universities in the subsequent editions⁴), whose 8 masters’ students have been selected for supporting Mind the Bridge in the international scouting and support to local companies for the finalization of Proof of Concepts (PoCs). Fifth, international startups and scaleups that have been “matched” with local SMEs. The ultimate goal is to map the innovation needs of local companies operating in strategic industries (chemistry, waste management, carbon capture & storage, energy efficiency and safety, renewables). Once the needs of local companies are mapped, startups and scaleups will be selected to allow local companies to onboard technological innovation mainly through Venture Client model.

Results. The author is involved in the investigation of “ORA!” since its creation, and interviews of involved actors are still in progress. Being “ORA!” in its infancy, results at the time of writing include only the “starting phase” of the activities at the ecosystem level. Data will then be collected longitudinally over the next few years, allowing to conduct a longitudinal in-depth study. Moreover, it is important to underline the uniqueness of the setting under investigation, and, notably, of the primary insights. As mentioned, extant studies on OI ecosystems mainly focus on single-case studies and concentrate on a single firm, on its effort in adopting OI, and on the subsequent ecosystem evolution. In our case, the selected setting constitutes a novelty, and allows the investigation of the creation of an OI support initiative born from the joint agreement between a large firm and a municipality. Furthermore, to the best of our knowledge, this study constitutes the first attempt in considering all ecosystem members (i.e., large firm, SMEs, University, Municipality, startups and scaleups) as units of analysis. In addition, it is important to underline how relevant it is to analyze an ecosystem development initiative since the very beginning of its existence. Not the least, preliminary results suggest that ecosystem support initiative like this strongly facilitate corporate-startup collaborations and SMEs openness. SMEs are resource constrained, and traditionally struggle to engage in OI practices. However, this support initiative appears to be helping them.

Research limitations. The present study is based on the analysis of a single case-study, thereby acknowledging all associated difficulties for generalization. Besides the fact that this qualitative investigation is still in progress (specifically, under the longitudinal perspective), it opens up for further inquiries that could lead to a set of propositions to be investigated with a broader spectrum of cases.

Managerial implications. This study has several important implications for managers and organizations running Open Innovation activities within an ecosystem or planning to implement them. For ecosystem orchestrators, the adoption of OI practices should be organized in way that permits all ecosystem members to profit from open collaborations, with the aim of overcoming the standard way of opening up to OI, allowing all ecosystem members to benefit from the collaboration with startups. Moreover, policies should be implemented to facilitate the creation of joint initiatives with large firms as a way to allow local business to foster entrepreneurship. Successful innovations depend on the availability of complementary and resources and capabilities (Sun et al., 2019); therefore, OI support initiatives devoted to

² Eni is a leading Italian multinational energy company operating in the oil and gas sector. Established in 1953, Eni is one of the world’s largest publicly traded oil and gas companies, with operations spanning across the globe.

³ Founded in 2007, Mind the Bridge (MTB) is a global organization providing innovation advisory services and products for both startups and corporates. MTB’s mission is to foster the creation and development of sustainable and global entrepreneurial ecosystems by offering specific programs designed to unite startups and corporates. In addition, the company regularly publishes research reports on the world of technology scaleups.

⁴ The first round of “ORA!” initiative was successfully concluded; Eni and the Municipality of Ravenna are currently working on the second round. The initiative is intended to become a permanent project.

facilitating knowledge and resource sharing are essential for ecosystem development and support. This study will provide managers with practical evidence on the relevance of an inclusive framework that enables different actors and stakeholders to engage proactively as an effective approach to employ OI and to foster entrepreneurship.

Originality of the paper. As anticipated, the novelty of this study relies on both the case selected and the level of analysis adopted. The selected case provides the opportunity to theorize upon an unusual phenomenon, that is the large firm-municipality joint decision to support their surrounding ecosystem by developing an OI ecosystem support initiative. Accordingly, investigating the adoption of OI by all the actors involved in the ecosystem and the subsequent evolution of the ecosystem provides novel perspective that will contribute to the literature on IEs.

Moreover, OI practices showed to be constantly evolving (Chesbrough, 2017; Vanhaverbeke and Gilsing, 2023), thus requiring to be studied in the moment they are adopted. Accordingly, the present study contributes to the OI field of research by providing novel perspectives on OI implementation and evolution.

Empowering Digital Entrepreneurship: Regulatory Governance in Platform Ecosystems

MUHANAD HASAN AGHA¹ VLADIMIR KOROVKIN² SVETLANA MIRONYUK³

Abstract

In this paper, we investigate the regulatory governance frameworks that can empower digital entrepreneurship and enhance the welfare of entrepreneurs operating on digital platforms. The study explores the complex dynamics of power imbalances within these ecosystems and examines potential regulatory interventions to address them.

Key words: platform; governance; digital entrepreneurship; empowering; business ecosystem

Framing of the research. *The proliferation of digital platforms has revolutionized the entrepreneurial landscape, providing unprecedented opportunities for innovation and value creation. However, these platforms are often characterized by asymmetrical power dynamics, with platform owners exercising significant control over the entrepreneurial endeavors within their ecosystems. This research seeks to understand the structural underpinnings of these power imbalances and identify regulatory mechanisms that can empower entrepreneurs and promote their welfare.*

Purpose of the paper. *The primary objective of this paper is to examine the role of regulatory governance in fostering a more equitable and conducive environment for digital entrepreneurship. Using existing literature, qualitative interviews with entrepreneurs, and analyses of regulatory frameworks, the study provides policymakers, platform owners, and entrepreneurs with actionable insights.*

Methodology. *The methodology is based on a mixed-methods approach that integrates a thorough review of academic literature with qualitative interviews with entrepreneurs. The literature review provides a theoretical framework for understanding the dynamics of digital platforms and entrepreneurship, while the interviews offer practical perspectives on the challenges faced by entrepreneurs within these ecosystems. Regulatory frameworks are analyzed to assess their effectiveness in addressing the identified challenges.*

Results. *The results indicate that entrepreneurs face a significant power imbalance vis-à-vis platform owners, who can impose unilateral changes in competitive conditions on the platform. The power wielded by platform companies stems from the distinctive structural features of the platform, where the owner monopolizes the possession of the technological infrastructure enabling them to build control algorithms overall performance aspects. Given its central position, the platform can determine what information should be provided to any users, and what should not. This ability to analyze, reassemble, and process data and information for the platform allows it to influence interests and actions. Consequently, one of the primary risks confronting entrepreneurs is that the platform owner may decide to compete with them, as they can direct traffic towards their offerings. What further exacerbates power differentials within digital platforms is the largely negative (and possibly enabling in crucial aspects) stance taken by governments in avoiding regulatory oversight and intervention. Thus, the research findings affirm that the presence of advanced forms of regulatory interventions, such as polycentric governance, which considers the horizontal and vertical relationships among different elements, can lead to empowering digital entrepreneurship and enhancing entrepreneurs' well-being.*

Research limitations. *One potential limitation of this research is the scope of regulatory frameworks analyzed, which may not encompass all relevant jurisdictions and platforms. Additionally, the qualitative nature of the interviews may limit the generalizability of the findings. However, efforts will be made to mitigate these limitations through rigorous methodology and triangulation of data sources.*

Managerial implications. *The findings of this research will have important implications for policymakers, platform owners, and entrepreneurs. Policymakers will gain insights into the regulatory interventions needed to foster a more inclusive and competitive digital entrepreneurship ecosystem. Platform owners will understand the importance of governance mechanisms in promoting entrepreneurship and innovation, while entrepreneurs will receive guidance on navigating the regulatory landscape and advocating for their interests.*

Originality of the paper. *This paper contributes to the existing literature by synthesizing academic research with practical perspectives from entrepreneurs, offering a comprehensive analysis of the regulatory governance frameworks*

needed to empower digital entrepreneurship. By bridging the gap between theory and practice, this research provides original insights and actionable recommendations for promoting entrepreneurship and improving the welfare of entrepreneurs within digital platforms.

The Governance of Entrepreneurial Ecosystems: Ecosystem Manager or Ecosystem Act?

GABRIELE IANIRO¹ MICHELE MODINA²

Abstract

While different studies enriched our knowledge of the entrepreneurial ecosystem (EE) framework, with insights concerning an EE's definition, theoretical constructs, constitutive elements, structure, and processes, the development of EEs remains a tricky challenge for both researchers and practitioners, as many debates and unanswered questions still inhabit the literature. Among those, there are still relevant questions regarding an ecosystem's evolution and governance, which prevent us from fully understanding the dynamics that underlie an EE's development. Especially, some related concepts seem to be either misused, used too loosely or in contrasting ways, requiring therefore better conceptualization.

The aim of this paper, thus, is to provide more clarity in the literature by problematizing the concepts of governance and management in EEs, so to provide new points of view for future research on an ecosystem's development and evolution. Our preliminary findings show that the necessity for management and governance reside intrinsically in the EE definition, given the need for coordination and monitoring to guarantee its sustainability. As meta-organizations, then, EEs, not only need governance but, most of all, need the responsibility for its monitoring and maintenance to be democratically assigned.

Keywords: entrepreneurial ecosystem; governance; management; problematization; ecosystem development.

Framing of the research. In the last twenty years, the framework of entrepreneurial ecosystems (EEs) has emerged as a theory and tool to explain the mechanisms behind economic growth at the regional level concerning entrepreneurship and innovation development processes (Alvedalen & Boschma, 2017; Cavallo et al., 2019; Cao et al., 2021; Thai et al., 2023). In particular, the framework tries to do that by describing how different actors, factors, artifacts, and the relations between them can foster the development of high-growth entrepreneurship in a defined region.

In view of the growing problem of disparity in terms of economic and social development between different geographical areas (World Economic Forum, 2024) and given that the increasing pace of technological progress is creating the need, for regional and national governments, to be able to exploit the potential of innovation to the fullest in order to ensure the competitiveness of their territories (Johannessen & Sætersdal, 2020), the creation of EEs has become a policy priority for governments around the world.

As of today, different studies advanced the literature for what concerns an EE's definition and theoretical constructs (Isenberg, 2010; Mason and Brown, 2014; Acs et al., 2017; Brown & Mason, 2017; O'Connor et al., 2018), constitutive elements and structure (Stam, 2015; Adner, 2017; Carayannis et al., 2017; Stam & Van De Ven, 2021), and processes (Dubina et al., 2016; Spigel, 2017; Spigel & Harrison, 2018; Wurth et al., 2023).

Despite the progress made by academics, however, the development of EEs remains a tricky challenge for both researchers and practitioners, as many debates and unanswered questions still inhabit the literature (Cavallo et al., 2019; Wurth et al., 2022; Cho et al., 2022).

Among those, there are still relevant questions regarding an ecosystem's evolution (Cho et al., 2022) and governance (Colombo et al., 2019), which prevent us from fully understanding what are the dynamics that underlie the development of a successful EE, and who should play the management role.

On the one hand, indeed, some studies offered ideas about the possible evolutionary processes of entrepreneurial ecosystems, although leaving little room for operationalization in the concepts, as they slightly link them to the phenomenon of planning and governance (Mack & Mayer, 2016; Kantis & Federico, 2020; Cantner et al., 2021) apart from Cho et al. (2022).

On the other hand, the literature is contrasting in its opinions regarding the type(s) of governance and governance approaches which characterize EEs: formal and informal, top-down and bottom-up, relational and/or hierarchical, fixed in time or evolving (Colombelli et al., 2019; Colombo et al., 2019; Cunningham et al., 2019; Scott et al., 2022). Such studies, in fact, slightly address the issue of the development of entrepreneurial ecosystems, which still remains a blurry

² University of Molise
e-mail: michele.modina@unimol.it

problem both to practitioners, policymakers and academics. Moreover, they do not seem to agree regarding both the necessity for and possibility of management as well as the responsibility for management by ecosystem actors.

Considering these issues, then, what the presence of many different points of view on the topic tells us is that there is still a need for a solid conceptual clarification regarding the manageability of an EE, as well as an adequate definition and delegation of responsibility for governance in this sense. Concerns, these, which have a major role in defining a solid basis for the developmental and evolutionary dynamics of EEs, especially given the call for more empirical works in the field.

Purpose of the paper. The purpose of this conceptual work, then, is to fill this gap and advance the knowledge regarding the development of EEs by problematizing the concept of their governance and management. In order to do that, we first make clarity on the definition of entrepreneurial ecosystems, by critically analyzing it, and after that questioning whether an EE can or should be managed, who should eventually be responsible for its management (as well as what should be the configuration of governance for EEs), and how responsibility for performance can be and should be distributed in the entrepreneurial ecosystem.

In particular, given the abundance of papers that consider as given both the possibility of governance and the possibility for some of the organizations of the quadruple helix (Carayannis & Campbell, 2009) to “orchestrate” the ecosystem, the study tries to understand whether a sort of “Ecosystem Manager” (or orchestrator) or an “Ecosystem Act” (or act of taking responsibility) result necessary for the development of entrepreneurial ecosystems.

Methodology. For the purpose of this paper, we follow a multistage process, following Alvesson & Sandberg (2010; 2020) which consider six steps for the problematizing review: 1. Identify a domain of literature; 2. Identify and articulate assumptions; 3. Evaluate articulated assumptions; 4. Develop alternative assumptions; 5. Consider assumptions in relation to the audience; 6. Evaluate the alternative assumption ground.

Especially, it proceeds by “[...] reading broadly, but selectively [...]”, challenging points of departure in the literature, and carefully analyzing a small number of selected high-quality studies that cover a broad range of topics.

That being said, given the complexity of the ecosystem concept, and taking inspiration from Laasch et al. (2020) and Alvesson & Blom (2022), who highlight the necessity to shed light on some big, ambiguous concepts in order to make clarity in the research field, we carry out a preliminary stage which focuses on making clarity on the definition of entrepreneurial ecosystems, which allows us to identify precisely the domain literature and to identify and articulate assumptions.

In particular, for this preliminary stage regarding the definition of entrepreneurial ecosystem, we take inspiration from Laasch et al. (2020) for the identification of domains, and we begin by adopting a systematic approach in order to be able to find the most adopted definition and “dissect” it, to identify the domains and the main assumption regarding the manageability of the EE and critically commenting them in order to develop alternative assumptions, which might take different paths depending on the results.

In this regard, we follow the process suggested by Tranfield et al. (2003), which involves three main phases of: 1) planning of the review (for which the need had already been previously identified and a proposal made) through the definition of a clear research protocol; 2) conducting the review, through the application of the research protocol, leads to the identification of publications and the selection of studies to be included in the review on the basis of the inclusion and exclusion criteria specified in the research protocol; 3) reporting and dissemination, through a detailed analysis of the publications included in the sample.

Considering the pertinence, we applied a multistage process similar to that of Wurth et al. (2022), but with some differences. First of all, unlike these authors, the selected database was Scopus. In this regard, although both Web of Science and Scopus represent the most widely used databases for bibliographic analysis, the latter is a better option in terms of the inclusiveness of the database, the user-friendliness of the interface, and wider and easier access to metrics that are more reliable and less susceptible to manipulation than Web of Science (Pranckutė, 2021).

Secondly, unlike the other authors, given the objective of this stage of analysis to understand the specific definition of entrepreneurial ecosystem, we focused exclusively on the concept of entrepreneurial ecosystem without including related concepts. In this sense, we refer to similar concepts such as the “startup ecosystem”, the “entrepreneurial system”, the “entrepreneurship system,” or the “system of entrepreneurship.” Therefore, the search by topic (title, abstract, keywords) was developed using a single keyword: “entrepreneur* ecosystem*.” The keyword has been defined in this way in order to include both the term “entrepreneurship ecosystem” and the term “entrepreneurial ecosystem”. The result was an initial sample of 2245 items in the period between 2006 and 2024. Of these, 1444 are journal articles, 56 books, 389 book chapters, 248 conference papers, 17 conference reviews, 54 reviews, 16 editorials and 21 data papers, erratum, letters, notes, and retracted articles. As in Wurth et al. (2022) we excluded books, book chapters, conference reviews and the 21 other items. In addition, we have excluded all releases that are not in English (49 records). This process left a total of 1713 articles, including journal articles, conference papers, reviews, and editorials.

We included not only journal articles, but also the remaining publications because, although the interest was to select high-quality publications, we were also interested in selecting publications that are as accepted and approved as possible by academics, considering that the subsequent steps would allow for further exclusion.

The second phase, on the other hand, follows precisely Wurth et al. (2022) and concerns the application of exclusion criteria based on the journal of publication. Therefore, the Scimago Journal Rankings were used in the latest 2022 edition. To select the most relevant journals, the top 25% of the journals in the following areas were selected: Business and International Management; Business, Management, and Accounting Miscellaneous; Management of Technology and Innovation; Strategy and Management; Economics, Econometrics, and Finance Miscellaneous; Economics and

Econometrics; Geography, Planning and Development; Social Sciences Miscellaneous; and Urban Studies.

This step is essential to include a more significant number of articles related to the areas that affect the concept of entrepreneurial ecosystem and, on the other hand, to ensure a higher scientific quality of the items in the database. This step, thus, resulted in a sample of 741 journals, of which 113 were represented within our initial sample.

In particular, it should be noted that to select the relevant journals, a comparison was also made between the Journals present within the sample that emerged from the selection and the ones present within the sample of articles found on Scopus. Taking into account that - at this stage of analysis - the objective of the systematic review is to identify the most influential and important articles in the literature on entrepreneurial ecosystems in order to extrapolate an integral definition, this comparison has also made it possible to include a tiny number of journals that, on the one hand, within the Scimago database are Q2, but have a ranking that includes them in the top 25% of the journals with the highest ranking. On the other hand, these journals are those in which some very relevant articles for reading ecosystems have been published. Finally, another addition was that of a journal that does not fall within the previously selected categories but within the marketing area (i.e., *Journal of Business Research*). This process then led to the selection of an intermediate sample of 652 articles.

Finally, further exclusion criteria were applied. First, we excluded all publications that do not explicitly reference the entrepreneurial ecosystem concept but use it only as the context in which the object of their research took place. Second, publications that refer to other constructs, such as the innovation ecosystem, digital entrepreneurial ecosystem, and sustainable entrepreneurial ecosystem, were excluded as well. Third, non-conceptual publications and all publications that did not have any definition of an entrepreneurial ecosystem were excluded. This process led to the definition of a final sample of 65 publications between 2006 and 2024.

Based on the sample emerging from the selection, the text was analyzed by first grouping the recurrent definitions, following some of the scrutiny methodologies presented by Ryan et al. (2003), and then conducting a critical analysis of the results. For what concerns the scrutiny process, first, we have been looking for repetitions between different definitions - and therefore, “[...] ‘topics that occur and reoccur’ [...] or are ‘recurring regularities’ [...]” (Ryan et al., 2003) - and then, net of repetitions, we proceeded to look for similarities and differences between the definitions. This analysis made it possible to identify the recurring and the less recurring themes to create an integrated definition.

Thanks to this process, we were able to: 1) reconstruct an entrepreneurial ecosystem definition; 2) “dissect” it and analyze it based on the recurring themes in order to identify the domains; 3) begin to critically comment on its components in order to find the necessity for governance in the definition and also understanding the main domain areas.

After this process, following Alvesson & Sandberg (2010; 2020), the paper will continue by selecting a few works included in the domain areas of the EE concept, consequently identifying the main assumptions regarding governance and management in an ecosystem, and evaluating them.

Finally, the paper will conclude with new research questions spinning out from the alternative assumption ground.

Results. Our preliminary results regarding the first stage of our problematizing review show that the most comprehensive and synthetic definition of EE is the one introduced by Stam (2015) and then updated by Kuratko et al. (2017). Moreover, from the comprehensive analysis of the definitions, among the different components we can highlight three main activities (or functions) that ecosystem actors and factors should perform: creating a favorable environment for productive entrepreneurship to proliferate, monitoring performance, and coordinating activities.

Considering this, then, although labeling entrepreneurial ecosystems as “organizations” is a conceptual extension, EEs can be conceptualized as “meta-organizations” that not only need governance but, above all, need someone who takes care of its monitoring and maintenance of the “ecosystem” organization: that is, a manager.

Research limitations. Although the study is in its early stages, the main limitations are linked to the lack of empirical and longitudinal studies in the sample of papers, which only allows us to work on hypotheses rather than facts. Moreover, given the small number of papers on which the problematizing review should be carried out (in the second phase of the review), the paper might exclude valuable works that could allow better conceptualization.

Managerial implications. Governance and management are the two main topics that allow the entrepreneurial ecosystem research to be operationalized. The development of entrepreneurial ecosystems, indeed, depends not only on our knowledge of “what” should be developed, and “how” and “when” to do it, but most of all on “who” should do it. Policymakers and top managers from organizations attaining the “quadruple helix” actors can benefit from this study by first understanding that an ecosystem should not only be managed but, most of all can be. Secondly, policymakers could use this study to direct funds and policies to the development of the type of organization that could be responsible for the development of an entrepreneurial ecosystem. Also, top managers from organizations in an entrepreneurial ecosystem could understand whether to redirect their investments in an ecosystem’s development, persevere in them, or create totally new organizations in order to reach this goal.

Finally, the paper has the potential to advance the literature regarding entrepreneurial ecosystems and, most of all, open new research avenues for what concerns an ecosystem’s development. The problematization, indeed, both makes clarity on the previous debates and inconsistencies and makes space for new avenues of research. In this case, given the early stage of the study, the preliminary results show that the study could help clearing the path for new studies concerning governance in entrepreneurial ecosystems.

Originality of the paper. As of today, while the literature of entrepreneurial ecosystems advanced with a wealth of studies, few of them critically reviewed the field (Alvedalen & Boschma, 2017; Brown & Mason, 2017; Cavallo et al.,

2019), mainly focusing on the difference between older or similar concepts. However, they did not focus on specific areas of the ecosystem concept (as in the case of governance) or systematically analyze the use of the definition in the literature. In this particular case, as anticipated earlier in the text, while other researchers introduced different views on governance and management in an entrepreneurial ecosystem, either setting governance as the main subject of the study or including governance in the discussions, they not only proposed different approaches but most of all seemingly gave for granted some considerations regarding governance, that instead are the main subject of this paper.

A comprehensive exploration of the knowns and unknowns of Private Equity Secondary Markets

MICHELE LERTORA¹ CRISTINA DE SILVA² MARGHERITA MIETTO³ ANNA GERVASONI⁴

Abstract

In parallel with the growth of primary Private Equity (PE) markets, secondary markets have emerged as a tool to provide liquidity to Limited Partners. Over the last years, a decrease in exit activities implied more difficulties for General Partners to distribute liquidity to their investors, thus driving to a higher demand for secondary markets.

This work aims to provide a comprehensive and systematic review of what has already emerged from academic studies and practitioner reports and to highlight current knowledge gaps, to propose several valuable research directions and to inform stakeholders of managerial implication related to this market.

Key words: private equity; venture capital; secondary markets; illiquidity; LP-led; GP-led

Framing of the research. Private equity funds are typically based on a contractual agreement between a General Partner (GP), who manages the fund and makes the investments, and Limited Partners (LPs), who agree to provide capital on demand to the GP. The lifecycle of a typical PE fund is usually 10 years or more, which implies that investors must commit capital and are generally locked up for the fund's entire life (Nadauld et al., 2019). However, LPs might wish to exit earlier on, if they need to rebalance their portfolios, external events (for instance a decline in public listings) leave them over-allocated to the PE asset class (denominator effect) or to reduce non-core managers or strategies or re-deploy to new vintages (Boyer et al., 2023, Albuquerque et al., 2018). Secondary markets then step in as a tool to provide liquidity to LPs.

Following an explosive growth of the primary private equity industry, which reached over \$20 trillion in assets under management globally (Bain, 2024), the secondary market experienced a substantial increase (Jefferies, 2024). Besides this, PE has encountered difficulties in distributing liquidity to LPs in recent years due to a sharp slowdown in exit paths, less than half the proportion of five years ago (Preqin, 2024). Currently, the unrealized value amounts to \$3.2 trillion and consists of 28,000 unsold companies, more than 40% of which are four years old or older, generating a liquidity problem (Bain, 2024). Fewer exit opportunities, in turn, lead to decreased distributions for LPs, thereby creating a challenging fundraising landscape.

In this regard, the secondary market plays a vital role for both GPs and LPs, providing an array of tools that they can use to manage their own liquidity needs as well as those of their stakeholders. Although the secondary market represents only 4 percent of the total capital raised by the PE industry as a whole in the last 15 years and currently deploys about \$100 billion of liquidity annually, the market is expected to continue to grow in the next years (Jefferies, 2024). Indeed, secondary funds raised 92% more capital in 2023 than they did in 2022 (Bain, 2024) and invested 4% more in 2023 compared to 2022, reaching \$112 billion (Jefferies, 2024), as shown in figure 1.

Figure 1. Private Equity secondary market investments (mld, \$)

Source: Personal elaboration on public data

PE secondary markets are usually characterised by two sub-strategies: (i) LP-led deals, i.e. a transaction in which a LP sells its stake in a (multiple) PE fund(s) to a secondary buyer, which replaces him in both duties and rights, and (ii) GP-led deals, which are originated directly by the PE sponsor and are aimed at reorganizing their portfolios while offering liquidity solutions to their current LPs.

Purpose of the paper. The present systematic review, which is still a work in progress, moves initial steps in reorganizing existing literature by detecting thematic connections and highlighting uncovered issues deserving further attention. More specifically, this research aims to contribute to the academic understanding of the secondary market in private equity and to provide valuable insights from current existing literature. This review provides a comprehensive and detailed overview of what has emerged in the outlined areas from academic and practitioner sides. This effort marks a crucial move towards bridging the current knowledge gaps, making a significant contribution to the scholarly dialogue, and proposing a valuable research direction for further investigations in the evolving landscape of the private equity secondary market.

Methodology. Our research has been developed through a systematic review of existing academic literature as well as of “grey literature” and practitioners reports. We also interviewed some senior PE secondary managers to understand principal topics and to validate our insights and future research directions.

Despite the growth of the market, academic research on the topic is scarce, in particular on GP-led transactions.

This gap represents a distinctive opportunity to contribute to the existing body of knowledge, providing new perspectives and interesting research insights.

In this regard, we developed a comprehensive review that not only sheds light on the complexities of this dynamic market but also highlights its potential as a rich line of inquiry, marking a significant contribution to the field.

In the initial phase of our exploration, we selected the most relevant research articles on the secondary market in private equity retrieved by different database such as Scopus repository, Web of Science, SSRN and Google Scholar.

This analysis unveiled that the academic literature has predominantly focused on LP-led transactions, underscoring the pivotal role of secondary market for PE investors. To broaden our understanding and capture other significant emerging evidence in this area, we include in our research the analysis of key market reports provided by leading industry players. This extension of our analysis revealed that the transactions led by General Partners (GP-led transactions) have begun to represent half of the market, while being quite entirely understudied.

Furthermore, to depict some preliminary evidence on secondary players performance, we retrieved data from publicly available sources and manually assembled to build the final sample of 192 observations. Each of them represents a PE fund active in the secondaries market with year of final close between 2000 and 2023, with details on geographical location, fundraising activity, and performance of 192 funds managed by 54 GPs at the global level.

Results. PE secondary markets in origin were composed almost exclusively of LP-led deals, i.e. a transaction in which a LP sells its stake in a (multiple) PE fund(s) to a secondary buyer, which replaces him in both duties and rights, i.e. obligations for remaining capital calls as well as being entitled to receive future distributions (Mason & Utke, 2023; InvestEurope).

Following the growth of LP-led deals in the last decade, which also surged after the global financial crisis, few academic studies studied specifically this segment of the market. Secondary buyers are seen as a provider of liquidity to selling LPs, typically in exchange for an “illiquidity” premium: they buy from sellers at a discount on NAVs, which is higher in crisis times (Hege & Nuti, 2011) or when the demand for liquidity exceeds the supply, and outperform sellers by a market-adjusted 5 percentage points annually (Nadauld et al. 2019).

Determinants of illiquidity in the secondary market are explained by specific fund characteristics that make its LPs more vulnerable in case of liquidity shocks. For instance, lower bids (i.e. higher discounts on NAVs) are associated to

young funds, which present the highest risk of funding future capital calls (Albuquerque et al, 2019), whereas larger buyout funds with smaller remaining commitments and larger remaining distributions have higher secondary market demand (i.e., lower discounts) (Kleymenova et al, 2012). Furthermore, fiscal policies also affect the size of the illiquidity discount, as different legal structures of PE funds and different jurisdictions can affect the magnitude of the tax discount (Mason & Utke, 2023).

On the contrary, there is almost no academic research on GP-led deals, which are a relatively new market phenomenon (Mason et al., 2023). Unlike LP-led transactions, GP-led deals originate directly from GPs, which aim primarily at reorganizing one or more funds under their control while offering liquidity solutions to the current LPs.

Although GP-led secondary transactions include different strategies (team spinoffs with assets, portfolio strip sale, tender offer, preferred equity) that have been used in the industry for more than 15 years, over the last few years continuation funds have become the most common structure. Continuation Funds (CFs) address situations where an asset (single-asset Continuation Fund) or a collection of assets (multi-asset Continuation Fund) are transferred from the original fund into a Continuation Fund managed by the same GP (Gottschalg 2023). The latter transfers assets from the original private equity fund to a new continuation fund at a discount. Although LPs have the option of leaving the primary fund, they are often offered the opportunity to reinvest in the continuation fund. The practice of rolling portfolio assets into so-called continuation funds offers the opportunity to LPs to continue investing in portfolio companies whose potential might be further exploited and gain an incremental return on the initial investment. However, it might also be argued that GP-led deals represent a “last-resort” exit route to distribute cash to their LPs, when other exit strategies are not viable due to external market conditions.

Notwithstanding the empirical relevance of the topic, several potential research questions on GP-led deals (pricing, performance, value creation, conflict of interests among stakeholders) remain unanswered so far.

In terms of pricing compared to NAVs, LP-led deals usually report higher discounts than GP-led deals. Among the latter, single-asset CF report lower discount to NAV than multi-asset due to their quality. The demand for quality over diversification is evident in the success of single-asset transactions, indicating that while these deals may not explicitly carry a “control premium” like in strategic sales, the quality of the underlying asset and alignment with GPs can drive favourable pricing (Farman 2023).

Bearing this in mind, empirical studies should appraise if the price paid for portfolio companies in GP-led transactions is close to the NAV and which are the main determinants of such a price.

Performance-wise, some market participants may have historically viewed GP-led transactions as a way for underperforming managers to extend the life of their holdings while distributing cash to original LPs. However, a recent white paper (HEC, 2024) find that CFs perform in line with buyout funds, with a lower dispersion of performance. This is consistent with the view that the portfolio companies transferred to the CFs are already known by the GP and management team and has already proven to perform well, hence generating less risky outcomes. Moreover, multi-asset GP-led deals should offer more diversification and risk-adjusted returns and share more similarities with LP-led transactions, as it is a way for the GP to anticipate the liquidity needs of its LPs.

Overall, private equity funds’ NAVs are not objective market-based values but can be subject to GPs manipulations (Nadauld et al, 2019). This leads to the necessity to perform a comparison of annualized returns of sellers and buyers also for GP-led deals, following the methodology of Nadauld et al. 2019 for LP-led deals.

The continuation vehicle typically resets the fund term and includes a new incentive structure for the GP in order to maximize alignment with the new LPs of the continuation fund. In almost cases, the GPs are typically requested to roll over 100% of their carried interest accrued into the new vehicle and to directly contribute with their cash in a higher proportion compared to the one usually asked for primary deals, to ensure an alignment of interest. LPs of the continuation fund want to see that the GP behaves as a “net” buyer in the transaction. In situations where the GP does not reinvest their entire carried interest into the new fund, it should offer a thorough justification for not transferring their full earned carried interest (ILPA 2023). This entails questions on potential different outcomes and conflict of interest around this topic.

From LPs’ viewpoint, the secondary buyers involved in CFs, especially single-asset, can benefit from the GP’s knowledge of the underlying asset, collaborate with the GP to further enhance the value of the asset and negotiate deal terms that more closely align the interests. This can reduce information asymmetry compared to commitments to primary buyout funds, while at the same time reducing diversification, and this can raise questions on the characteristics of LPs interested in these markets, their strategy and their business model.

The operating performance of portfolio companies transferred to CFs is another area of research deserving attention: do GPs transfer companies where value creation has not been fully reached and will be very high in the future, or is this transfer mainly realized to reach an exit, independent of adverse market conditions in the IPO market or the debt capital markets, for the existing LPs? Future studies should investigate if the operating performance of portfolio companies in the CFs is comparable or even higher to that reached during the holding period in the primary fund. CFs, in particular single-asset, could be closely compared to secondary buyouts (SBO). Academic literature previously focused on the operating performance of portfolio companies subject to SBO transactions, which involve portfolio companies sold from one GP to a different GP, finding that secondary buyouts display operational performance improvements comparable to

those of primary buyouts (Achleitner & Figge, 2012) and not significantly different from that of the peer group (Bonini, 2015).

Furthermore, more drivers of GPs willingness to realize continuation funds should be explored. For instance, future research could explore whether GPs who are in the process of fundraising a new fund are more inclined to initiate GP-led transactions on its previous fund, as this could help to improve their performance measures (i.e. DPI) and thus improve their likelihood to fundraise.

We also provide some preliminary general insights on the distribution and variability of performance data of secondary deals. Summary statistics for fund-level fundraising activity and performance are displayed below (Table 1).

Table 1. Summary statistics.

Variables	Obs.	Mean	Std. Dev.	Min.	p25	Median	p75	Max.
Funds raised (M; \$)	192	2,090.14	3,303.08	16	364.05	837.5	2,455	22,700
IRR	192	0.18	0.17	-0.32	0.09	0.15	0.23	1.30
TVPI	184	1.57	0.61	0	1.30	1.49	1.68	5.84
DPI	184	0.96	0.65	0	0.38	1.01	1.43	4.02

As emerges from Table 1, observed funds display wide variability in terms of fundraising activity. Overall, the mean raised amount totals \$2,090 M, ranging from a minimum of \$16 M to a maximum of \$22,700 M. The large gap between these two points and the high standard deviation indicates that fundraising activity suffers from substantial variation. Moreover, by comparing the mean with the median, we can easily see that the distribution of raised funds in our sample is positively skewed, suggesting that most funds have collected relatively small amounts while a few of them have attracted significant capitals from investors.

This trend may be partially explained by the high concentration of the secondaries market. Indeed, our analyses reveal that more than 50% of the total funds with available data with vintages between 2000 and 2023 are managed by only 4 out of 54 GPs.

As to performance, observed funds report an average IRR equal to 18%, with substantial fluctuations in the period considered. From Table 2, it is possible to clearly discern the evolution of fund returns across the different phases of the secondaries market, looking at different vintages. Throughout the 2000s, namely the decade in which the industry was dominated by LP-led deals, the average yearly IRR decreased, as more buyers approached the market and discounts on NAV narrowed, thus increasing competition, and offering more bargaining power to the seller.

Then, the mean funds' performance started to increase again around the year 2009, when the effects of the global financial crisis implied that more sellers approached the secondary markets. Starting from 2016-2017, when GP-led deals started to grow, returns of secondary funds started to increase as well as standard deviation. This is coherent with intrinsic characteristics of GP-led deals compared to LP-led, as the former should generate higher returns and greater risk as it entails less diversification. Eventually, data of the last 3 years show that the demand for liquidity of LPs grew due to fewer exit and distributions, with a stronger purchase power for secondary buyers reflected in higher returns.

Table 2. Evolution of IRR of secondary funds over time

Year	Mean	Std. Dev.	Min.	p25	Median	p75	Max.
2000	0.19	0.13	0.08	0.08	0.16	0.34	0.34
2001	0.12	0.11	0.04	0.04	0.12	0.20	0.20
2002	0.14	0.04	0.12	0.12	0.12	0.20	0.20
2003	0.25	0.09	0.19	0.19	0.20	0.35	0.35

2022	0.12	0.38	-0.32	-0.32	0.33	0.35	0.35
2023	0.40	0.44	0.03	0.07	0.23	0.60	1.30

Research limitations. *The present research aims to investigate an entirely new line of research that finds no relevant studies in extant literature. For this reason, to collect a substantial but still a small number of papers, we used various databases such as (Scopus Repository, Web of Science, Google Scholar, and SSRN) combined with market reports and grey literature to get an overview of the research topic even on the practitioner side. Given the scarcity of current studies, the literature review presented here may not be exhaustive. This may leave several relevant open questions in addition to those emerging from the analysis. Given these premises, our objective was to collect initial insights regarding any aspect of this dynamic market, to provide other researchers with a comprehensive view of the market trend and give evidence of interesting future research insights to be further investigated.*

Managerial implications. *Private Equity secondary markets are intended to provide liquidity as well as strategic options to both LPs and GPs. As a relatively new and growing industry, few studies have been conducted so far. Nevertheless, the topic deserves attention as it has managerial implications for several stakeholders of the PE industry.*

First, LPs have historically embraced secondaries to rebalance portfolio exposure across strategies, geographies, vintages, and funds by selling their stakes in funds that no longer align with their current investment strategy or diversification objectives. Academic studies on LP-led deals show that secondary buyers typically outperform sellers, by buying at NAV discounts. On the contrary, there are no findings on the performance on continuation funds compared to original buyout funds. Further information on the performance of secondary deals is important for LPs to take informed decisions. Moreover, LPs need to understand different characteristics and business models of different sub-strategies of secondary buyers. Indeed, secondaries buyers executing LP-led deals should buy portfolios of LP stakes which entails portfolio companies close to an exit and thus should distribute in short time cash flows, whereas GP-led deals have a different rationale, in particular when looking at single-asset deals, as one would expect that the transferred asset would be held by the GP for another 4-5 years (a new holding period) in order to leverage on the yet unrealized value, and so LPs investing in secondary funds with this strategy should not expect distributions in short time.

An efficient secondary market would be particularly beneficial, besides LPs, for its implications for the venture capital asset class. Indeed, the surge in primary VC fundraising has allowed companies to stay private for longer because they can still raise ample cash without the full extent of the regulatory oversight and reporting requirements of the public market. Consequently, early investors, founders, and employees receiving company stock options in the early stage of the company face increasing difficulties in getting liquidity. Venture capital secondaries can be a way for venture-backed securities to solve this issue while remaining private.

From a GP perspective, secondary markets have played the role of providing ways to handle liquidity issues of LPs as well as rebalancing portfolios. In general terms, PE investors have a strong incentive to exit companies, which is driven by their compensation package, as their performance bonus (carried interest) is dependent on realized distributions to LPs and not on NAVs as it is for hedge funds' managers. The decision to roll-over their carried interest in a continuation fund, as well as providing relatively high new equity commitment to show to new LPs their commitment, is a pivotal choice that should be guided by the awareness of the still unrealized value in portfolio companies, or by a strong pressure from the LPs of the primary fund to receive distributions and the unavailability of other exit strategies. Additionally, through secondary transactions, especially those led by GPs, the alignment of interests between GPs and new LPs can be facilitated, with the former often reinvesting a significant portion of their accrued interest in the new vehicle.

For entrepreneurs interested in accessing PE, the institutionalization of an efficient GP-led market might be seen as a tool that reduces the perception and the risk to be forced by the GP to an external sale within about a 5-year period, avoiding the organizational and managerial consequences that a new buyer would imply, because the GP would have more flexibility to hold stakes longer if a growth path is undergoing.

Moreover, efficient secondary markets would have an impact on individuals. As the PE industry is growing, also the exposure of individuals on the asset class is booming, and the emerging of new digital platforms could accelerate this trend. However, one of the major issues for this “democratization” of the asset class is its intrinsic illiquidity, which can be improved by secondary markets.

From an industry perspective, the growth of AI could drive a boom for the industry. Since LP-led deals have an intensive data-driven process, it can be massively accelerated and automatized, decreasing the costs of due diligence, limiting human errors, improving efficiencies, and allowing secondary buyers to get more exposure to transactions.

From a policymaker perspective, the growth of PE secondary markets and over the last years of GP-led secondary transactions has attracted regulatory interest. As secondary markets entail potential asymmetry of information and conflicts of interest among various stakeholders, regulations should deal with the price-formation and fair-value appraisal of the deals.

Originality of the paper. *The research focuses on the PE secondary market that has not been extensively explored in academic literature. While LP-led deals have received considerable attention, GP-led transactions, the dynamics of liquidity provision, and the strategic motivations behind LPs' and GPs' participation, remain less examined. By delving into this understudied area, the paper addresses a gap in the current body of knowledge, offering insights into the complexities and nuances of secondary markets that are not widely investigated. This review opens multiple avenues for future research, serving as a catalyst for further investigation and contribution to the field.*

Unveiling the Pitfalls of Entrepreneurial Team Diversity: Insight from a post-mortem analysis of failed start-ups

ADELE PARMENTOLA¹ MICHELE COSTAGLIOLA DI FIORE²

Abstract

Entrepreneurial teams have received increasing attention in the academic debate. Diversity has been identified as one of the key characteristics that have a significant impact on start-up performance, being a double-edged sword. Despite the continuing interest in the topic, some questions remain unsolved. Existing studies provided more and more robust evidence for the positive effects of diversity than the negative ones. In addition, the relationship between diversity and performance has always been analyzed as static rather than dynamic, with a lack of research considering the stages of start-up development when analyzing the negative effects. To fill this gap, we aim to investigate which team diversity characteristics lead to start-up failure, considering the different stages of development. Based on interviews with founders of failed start-ups collected on the Failory database and applying a post-mortem analysis, we found that age, passion, vision, focus, and motivation diversity are the most critical factors in the transition of start-ups from one stage of development to another contributing to their failure. Our study provides a wide range of important implications for theory and practice. This is the first study to look specifically at the negative effects of diversity from a dynamic perspective, enriching the extant literature with a new theoretical framework. We also provide guidelines for managers involved in the start-up creation process who must be aware of the role of team characteristics and, in particular, team diversity, considering the issues, dynamics, and characteristics regarding the different stages of startup development.

Keywords: *entrepreneurial team diversity, start-up failure, stages of development, post-mortem analysis*

Framing of the research. *The entrepreneurial teams, defined as “two or more individuals who have a significant financial interest and participate actively in the development of the enterprise,” have attracted the attention of scholars from different domains representing a vast and interesting area of investigation (Horvatinovic et al., 2023). In particular, the role of the entrepreneurial team in start-ups has received increasing attention in entrepreneurship, entrepreneurial behaviors, and strategic management literature (Sundermeier and Mahlert, 2022). This growing attention stems from the fact that most start-ups are launched by a team rather than a hero entrepreneur (Knight et al., 2020; Yang et al., 2022). It has been demonstrated that teams have more resources, knowledge, and skills than individuals to deal with the various challenges they face at different stages of a firm’s development that require complexity and flexibility in decision-making (Chowdhury, 2005; West, 2007). More recently, research has recognized the importance of entrepreneurial teams and their characteristics in shaping new venture performance (Zhou and Rosini, 2015; Sundermeier and Mahlert, 2022). Drawing on the resource-based view and upper-echelon perspective, these studies suggest that the quality of human resources in the management team is crucial in predicting firm performance (Hambrick and Masons, 1984; Barney, 1991). Thus, the entrepreneurial team possesses intrinsically valuable and difficult-to-replicate human capital that can serve as the basis for the competitive advantage of new ventures (Barney, 1991). Team diversity is one of the characteristics that has attracted the most interest among scholars. More specifically, diversity at the team level is defined as “the distribution of differences among the members of a unit concerning a common attribute” (Harrison and Klein, 2007, p. 1200).*

The literature has classified the diversity variables according to three broad categories (Zhou and Rosini, 2015): demographic diversity, including age, gender, and ethnicity; informational diversity, including education and experience; and personality diversity, including different personality traits such as motivation, passion, and vision. These characteristics were related to various performance indicators, including team-level measures such as team efficiency and effectiveness, team productivity, team creativity, and team decision-making (Kollmann et al., 2017; Hou et al., 2021; Zhang et al., 2022; Ma et al., 2022) and firm-level measures such as survival, growth, innovation, external funding, and financial performance (Debrulle et al., 2020; Wise et al., 2022; Box and Segerling, 2018; Biga-Diameidou et al., 2021; Zhou and Rosini, 2015)

Traditionally, diversity has been considered a double-edged sword. If it is true that it brings new perspectives and ideas to the entrepreneurial team, it is also the root of intra-team divergent behaviors that harm performance (Das et al., 2021). Following the theoretical foundation of similarity-attraction (Byrne, 1971), social identity (Tajfel, 1978), and self-categorization perspective (Turner, 1978), people are attracted to and want to interact with others who share their opinions and values because they see them as validation of their own (Byrne, 1971). Within teams, individuals identify and differentiate themselves from each other (Tajfel, 1978). Such categorization occurs when different subgroup members are perceived unfavorably (Turner, 1978). Also, according to the conflict view (Amason et al., 2006), diversity will lead to conflicts and undesirable outcomes because of disparate opinions and attitudes. Consensus is difficult to reach since team members frequently divide into subgroups with inadequate interaction and numerous communication issues. According to these perspectives, individual team members can quickly categorize different team characteristics, negatively affecting performance.

Delving deeper into the existing literature, some studies have suggested that age, educational background, and experience diversity negatively affect sales growth (Amason et al., 2006). Bjørnåli and Aspelund (2012) suggested that age and industry background diversity negatively affect new ventures' international growth in building early alliances. Pinelli et al. (2020) found that the co-founder's educational background diversity, which is associated with a high level of education, hinders access to funding. Also, the diversity of experience in the founding team hinders the probability of accessing external funding (Blank and Carmeli, 2020). According to the study conducted by De Mol et al. (2020), diversity in terms of intensity separation, particularly in passion for developing the firm and passion for founding, negatively affects the obtainment of external funding. Lastly, experience diversity and educational level diversity were negatively related to financial performance in terms of ROA (Zhang et al., 2017). In addition to the paucity of studies analyzing the negative effects of team diversity on performance, these studies suffer from a static rather than a dynamic approach. None of the studies in this research stream demonstrated at which stage of start-up development specific team diversity attributes negatively affect start-up performance. As literature analyzing the dynamics of the entrepreneurial team composition suggests, teams are not static entities, but they evolve typically following the development stage of the firm (Patzelt et al., 2020; Yusubova et al., 2020). For example, a study on technology start-ups suggested that a team with solid technical expertise is more appropriate for the initial idea and product development stages. In contrast, in the later stages of commercialization and growth, team members with both technical and commercial experience are more in demand to sell the product in the market (Yusubova et al., 2020). The study by Tzabbar and Margolis (2017) also suggested that a specific entrepreneurial team composition depends on the firm's development stage. In particular, the authors showed that the positive effects of the human capital of the founding team in terms of educational heterogeneity and experience are stronger in the growth stage than in the early stage of a start-up. Another study suggested that heterogeneity of team industry and start-up experience is essential for start-ups to move from conception to creation (Munoz-Bullon et al., 2015). In sum, some entrepreneurial team characteristics, activities, and processes may be more or less critical during the different stages of firm development (Patzelt et al., 2020).

Purpose of the paper. Although the relationship between entrepreneurial team diversity and performance has been widely discussed in the literature, several questions remain unanswered. Firstly, little is known about the negative effects of diversity, particularly in terms of which variables harm performance. Existing studies provided more and stronger evidence for the positive impact of diversity than the negative ones. In addition, the relationship between diversity and performance has always been analyzed statically rather than dynamically, which means that studies fail to consider the different stages of venture development when analyzing negative effects.

Based on the above, our study aims to explore which team diversity characteristics lead to start-up failure, considering the different stages of development.

Methodology. Consistent with our aim, we employ a multiple case study following a post-mortem analysis (Yin, 1984). Post-mortem means analyzing the outcome retrospectively, which means "research in the past." Conducting post-mortem analysis is intricate due to its multifaceted nature, finding applications across diverse domains. For example, it can be used to analyze the project's final product, as Zhang and Iyer (2007) reported, or to help simulate the software process to improve software design estimation (Aguilar-Ruiz et al., 2001). Thus, this approach was typically used as an instrument of knowledge management in small and medium software projects (Schieg, 2007). In our work, post-mortem analysis is carried out to achieve an understanding of start-up projects that come to an end. Specifically, we followed a document-based post-mortem analysis method suggested by (Ahonen and Savolainen 2010). According to the authors, this type of analysis follows three steps:

- 1) **Data collection:** We collected online interviews with founders of failed start-ups from the Failory's database (<https://www.failory.com/startups>). The database regularly releases weekly articles, interviews, and narratives detailing both the successes and failures of startup founders, ensuring continuous updates. The database contains over 200 interviews, so the website allowed us to set up filters to speed up data collection. Firstly, we only considered interviewing entrepreneurs from failed start-ups, excluding successful ones. Secondly, we only considered failed team-based start-ups since we aim to investigate the problems and issues in an entrepreneurial team that were crucial in start-up failure. Once these filters had been applied, we read each reported interview to further refine it by excluding those whose failure was unrelated to the entrepreneurial team's characteristics. We ended up with a sample of 10 structured interviews with founders of failed start-up. The interviews are based on open-ended questions, which collect a range of information both related to the demographic characteristics of the founders and information related to the start-up history, such as the birth of the idea and how it was implemented, when things started to go wrong and what

were the main causes of failure. The interviews were supplemented by additional online material such as podcasts, posts, or other online news to get a complete view of the start-up story.

- 2) Data analysis: We analyzed the cases using the available documentation of each start-up in the following way. As we researched and obtained different information, it was possible to triangulate the analysis by cross-referencing it. The cases were constructed by anchoring the information to the various stages of the firm's development; thus, it was possible to capture the critical moments and issues regarding these phases. Reconstruction of start-ups' history helped us analyze the case in deeper detail, obtaining a great understanding of what went wrong
- 3) Presentation of results: In this last step, we reported the analysis result.

Results. The analysis of the negative effects of diversity showed that they need to be contextualized and considered in relation to the start-up's development stage. The negative effects of certain aspects of diversity vary from one stage to the next and are critical factors in determining failure. More specifically, they do not allow the company to move from one stage of development to another. Thus, by adopting a dynamic perspective, we have identified different stages of development: idea conception, product conception and development, and launch.

The first interesting aspect to emerge from our analysis is the nature of the diversity factors that have a negative impact. While the existing literature highlights demographic or informational factors such as age, education, and previous experience as critical factors, our study shows that the critical factors are purely cognitive or personality-related and, to a limited extent, demographic factors. Another interesting aspect, from a dynamic perspective, is that the negative effect of these variables only manifests itself in the product conception development and launch phases. Diversity does not seem to have a negative effect in the idea conception stage. Five start-ups failed in the product conception and development stage, and the diversity of passion, vision, and focus are the most critical factors in this phase. Team members often become detached from the business concept, resulting in a loss of enthusiasm for their work. Conceiving and developing a product necessitates ongoing collaboration among team members, occasionally involving trial and error that can lead to internal discord and divergent perspectives. At times, the workload becomes so demanding and exhaustive that the focus shifts toward irrelevant aspects, leading to delays and disarray. The other five start-ups failed in the launch phase, where diversity in age, passion, and motivation were the most critical factors. This stage is critical as the company interacts with the target market to secure its initial profits and expand gradually. Nonetheless, outcomes may not align with expectations; internal technical issues can result in the product failing to meet market demands. Financial losses and missed growth opportunities have left the team lacking motivation or enthusiasm.

For greater clarity, we have summarized the results of our study in a framework that highlights the negative impact of key diversity variables at different stages of development. In particular, following a combined approach, we match the concept derived from the literature regarding entrepreneurial team diversity and the different stages of development of start-ups identified. Thus, the framework combines two aspects: the main entrepreneurial team diversity attributes classified as demographic, informational, and personality (Zhou and Rosini, 2015), and the different stages of development classified as idea conception, product conception and development, and launch (Diakanastasi et al., 2018).

Fig. 1: Theoretical Framework

Research limitations. Our study has several limitations. First, our study analyzes failed start-up documents available online, providing relevant information up to the company's launch phase because we could not gather information about the subsequent development stages. Exploring this aspect in more detail is necessary to understand better which diversity factors may be critical in the later stages of development. Furthermore, it would be beneficial to include a control sample of successful start-up companies in the empirical analysis to determine whether a potential reason for failure has the opposite effect in a successful case study.

Managerial implications. *From a practical point of view, we offer suggestions to managers and founders involved in a start-up creation process, showing that what is important is not only the entrepreneurial propensity but also the intrinsic characteristics of the people involved in the start-up as co-founders. Managers should pay greater attention to cognitive and personality-related diversity aspects rather than only demographic or informational ones. Understanding the varied viewpoints, passions, visions, and focuses within the team is vital for navigating the different stages of startup growth. Managing diversity is a continual process that necessitates constant monitoring and adjustments. Managers must be aware of the changing dynamics within the team and modify management practices accordingly to mitigate the possible negative effects of diversity as the startup proceeds through different stages of development. The proposed framework could be used as a practical tool for decision-making regarding diversity management within the entrepreneurial team, which is useful in identifying potential areas of concern and tailoring interventions or strategies accordingly to optimize team performance and mitigate risks associated with diversity.*

The findings of this study could be helpful for incubators or accelerators that support start-up creation. They should implement courses or boot camps to manage diversity in an entrepreneurial setting, providing diversity training and awareness programs to help team members understand the value of diversity and develop the skills necessary to work effectively in diverse teams.

Originality of the paper. *While existing studies have focused more on the positive results, our study focuses on the negative impact by identifying which diversity variables were decisive in the failure of start-ups. Moreover, since existing studies have always analyzed the effects of entrepreneurial team diversity on performance from a static perspective, our study combines the analysis of negative effects in a dynamic perspective, identifying which diversity characteristics were crucial in the transition from one development phase to another, thus leading to the start-ups' failure. Additionally, the framework represents an original contribution to the literature because it combines two aspects: the main entrepreneurial team diversity attributes classified as demographic, informational, and personality, and the different stages of development classified as idea conception, product conception and development, and launch. These aspects have always been considered separately in existing studies that consider the potential negative effect of team diversity on venture growth.*

Agility to Handle Dynamics of Business Transformation

GIUSEPPE PIRRONE¹ MARGHERITA MILOTTA² BIRGIT HAGEN³ MARTIN CLOUTIER⁴

Abstract

This study analyzes the challenges and solutions of agile transformation using Group Concept Mapping methodology (GCM). We selected executives from large companies, scaleups, and external stakeholders to grasp different perspectives. The GCM identifies key challenges and solutions, emphasizing the importance of holistic understanding and agility during transformation journeys. Employee engagement, strategic changes, and iterative approaches are all critical to success. Cultural change requires tools and stakeholder engagement to be effective. Our contribution fills a gap in the agility literature by providing actionable insights for managers leading transformation efforts in dynamic markets.

Key words: agility, transformation, holistic, GCM, VUCA

Framing of the research. *Geopolitical changes, economic instability, technical advances and environmental disasters are some of the characteristics of a changing world. In response to this dynamic environment, the phenomena and need for change have become a hot topic, attracting the attention of businesses and academics.*

In recent years, practitioners and scholars have focused on various transformation concepts, such as agile, digital, and sustainable transformation (Strode et al., 2022; Grass, Backmann, & Hoegl, 2020; Warner & Wäger, 2019; Beretta & Smith, 2023). Furthermore, scholarly research stresses the need of organizational and strategic agility in attaining a competitive advantage and driving organizational performance, particularly in volatile, unpredictable, complex, and ambiguous (VUCA) situations (Troise et al., 2022). It highlights an organization's ability to manage chaotic and changing business landscapes, allowing for the capitalization of market opportunities and timely threat mitigation (Li et al., 2021). Despite evidence of agility's benefits, scientific work on agile transformation, particularly implementation elements, is lacking. Work on related issues, such as digital transformation, emphasizes the relevance and relationship to agile transformation (Beretta & Smith, 2023; Li et al., 2021), even referring to agility as "the engine of organizational transformation" (Beretta & Smith, 2023). Our perspective of agile transformation is holistic, encompassing both the design and implementation aspects of transformation. Such a comprehension includes more than just fundamental agile approaches; it also goes to the strategic level. It refers to the organization's capacity to reconfigure its strategy, culture, or structure in response to changing external and internal circumstances (Prange, 2021). Firms that adopt agile transformation may adjust quickly and take proactive actions (Girod, Birkinshaw, & Prange, 2023; Teece, Peteraf, & Leih, 2016). Thus, agile can enhance corporate performance (Handscomb et al., 2020; Salo, 2017) and competitiveness (Teece, Peteraf, & Leih, 2016). By researching agile transformation holistically, an in-depth analysis of external and internal variables is critical to identifying drivers, problems, and potential solutions as the change evolves. Existing research on agile transformation mostly departs from situations of "environmental turbulence" (e.g., Prange, 2021; Li et al., 2021), as previously indicated. This is not entirely unexpected given today's fast-paced and unpredictable world, in which firms must negotiate rapid technological breakthroughs, fluctuating consumer preferences, and environmental disasters. More precisely, external variables may not only initiate rapid change, but they may also provide ongoing obstacles that necessitate adjustments along the route. Unlike the description of the external environment, the analysis of internal agile transformation drivers shows tremendous nuance and interplay, making orchestration in design and execution crucial. Top management support is seen as crucial to success (Beretta & Smith, 2023; AlNuaimi et al., 2022; Grass, Backmann, & Hoegl, 2020). Transformational leadership is also highlighted (Bass & Riggio, 2006), which complements employee empowerment (Grass, Backmann, & Hoegl, 2020; Strode et al., 2022). Transformational leadership is distinguished by the ability to build relationships with subordinates while also educating and motivating (Ramadan et al., 2023). Co-strategizing procedures and the quality of internal conversation thereby connect the aspects of agile transformation design and implementation. Although "openness" to external stakeholders might provide the same benefits, Morton (2023) cautions that their engagement may add problems such as information leakage, misunderstanding, duties confusion, and information overload. The mentality and culture of an open-learning business,

with its dedication to continuous improvement, promotes the development of an agile workforce (Strode et al., 2022), which is another essential factor in strengthening a company's flexibility and readiness for change (Conboy & Carroll, 2019).

Technology and technology (i.e., digital) skills are cited as enablers of agile transformation (Troise et al., 2022; AlNuaimi et al., 2022). The role of technology is defined as the ease of delivering and sharing relevant information for decision-making across internal and external stakeholders, functions, and processes (Li et al., 2021). Finally, agile transformation presents a strategic problem with conflicts that businesses and leaders must address. These tensions are related to the balance between existing and new ways of strategizing, organizing, and learning (Smith & Lewis, 2011), the exploitation of existing capabilities versus the need to build new ones, the oscillation between maintaining today's business and transforming into tomorrow's business, or deciding between the need for speed and an incremental and slower transformation process. Proactively detecting, analyzing, and managing conflicts and problems will aid in achieving a successful transition trajectory.

Purpose of the paper. The external environment is increasingly dynamic and uncertain, unexpected and disruptive events require the ability of companies to react promptly to change. Indeed, transformation is now a watchword for most organizations to survive both exogenous and endogenous changes (Uhl & Gollenie, 2016). Organizational agility assumes a key role in such a volatile and uncertain environment (Troise et al., 2022), and it is deemed to be a driver of the transformation process (Beretta & Smith, 2023). Scholarly work emphasizes the role of agility as a driver of transformation and the need for a comprehensive study of agile implementation (Beretta & Smith, 2023). Despite its strategic importance, the implementation of agile transformation remains a considerable challenge (Annosi, Foss & Martini, 2020). Given the scarcity of existing work, our study seeks to fill the gap in understanding the implementation side of agile transformation by investigating and answering the research question:

What are the conceptualizations and perceptions of the challenges encountered in agile transformation trajectories and what solutions can be envisioned to address them?

Methodology. To effectively address our research aim, we employed a mixed method called Group Concept Mapping (GCM), which is beneficial for estimating conceptual representations and testing perceptions of those representations (Rosas, 2017; Trochim, 2017). To estimate participant groups' conceptualizations of a specific object, system, or topic, it employs both multivariate statistical techniques (e.g., agglomerative hierarchical cluster analysis, or AHCA) and qualitative techniques (e.g., brainstorming sessions and group interviews). It is frequently utilized in planning and evaluating social programs, health programs and concerns, education, entrepreneurship, and quality process improvement, among other areas. Inductive work may be done to comprehend polysemous situations using GCM in exploratory work (Cloutier et al., 2019). Executives from scaleups, major, established businesses, and players from the larger ecosystem made up participants, who were carefully chosen. Scaleups evolve to stay agile, whereas large, established organizations start the process of transformation to become agile. Lastly, the stakeholder viewpoint makes it possible to get objective data. As this study indicates, the GCM includes research phases that are connected to certain particular activities. Idea generation and discussion on a focus request are part of phase 1. Phase 1 involves group discussions and phase 2 is researcher-centered and involves coding content and developing items representative of their experience. Phase 3 involves structuring and evaluating the items by participants who participated in phase 1 and other participants new to the research who had experience with agile transformation. Phase 4 involves using multivariate statistical methods to analyze the results, and Phase 5 involves answering the research questions and assessing the results for external validity. This phase is based on the experience of the participants.

Results. The results are composed of two main parts. First, the concept map which is a conceptual representation of the main transformation challenges and solutions that emerged through the six focus groups. Second, the pattern matches illustrate the rank ordering of the perception of each cluster's importance and feasibility.

The Group Concept Map (Figure 1) clearly shows that participants have placed Strategic Enablers at the center of the concept map. This cluster includes 5 items, for example, 'To make room and space for continuous improvement' (Item 88), and 'To clearly define actions and objectives to be achieved by sharing decision power and responsibility' (Item 69). The central cluster serves as a systemic "attractor", influencing dynamic interactions among all other clusters on the map (Trochim & Cabrera, 2005). It shares boundaries with surrounding clusters, denoting common characteristics. The overarching interpretation posits that it absorbs tensions arising from dynamic interactions among all clusters depicted on the concept map. For instance, Item 69 - 'To clearly define actions and objectives to be achieved by sharing decision power and responsibility' (Strategic Enablers cluster) may be seen to interact with Item 25 'To understand what the people in leading positions need to know and what to delegate' (Preparing Human Capital, Readiness and Trust cluster) and Item 84 'To support and let individuals and teams figure out solutions' (Team Integration, Cohesion, and Reach cluster). Thus, from a strategic point of view, the central cluster influences the other clusters.

Figure 1. The Group Concept Map

The cluster named *Strategic Enablers* contains five items. As anticipated, it is located at the center of the map, and it is the most strategic one. It encompasses a series of ‘intangible’ items that lay the strategic foundations for a proper transformative process (e.g., Item 69 - ‘To clearly define actions and objectives to be achieved by sharing decision power and responsibility’). This cluster can be considered as representative of dimensions that unpack overall transformation goals and facilitate or catalyze solutions for action identified in the other clusters on the map.

Action Enabling Tools and Processes is a nine-item cluster. Its items focus on actions needed to carry out an organizational transformation process. Consequently, attention is directed towards indispensable tools and processes pivotal in facilitating transformation, such as, ‘To (re)allocate resource (e.g., capital, human, financial, etc.)’ (Item 1); ‘To do an organizational maturity level assessment, (whether informally or formally)’ the attention to rules and careful planning of the transformation (e.g., Item 8 - ‘To have micro-planning in fast transformation’), and the role of supporting tools, such as ‘flexible systems (e.g., IT systems), as the backbone of transformation’ (Item 2).

The cluster on *International and Local Stakeholder Engagement* has ten items. This cluster expresses a bilateral way of engaging with the external environment, both in terms of the international context and external stakeholders’ engagement more broadly. This cluster emphasizes the importance of the international context to sense opportunities or assess the current strategy (e.g., Item 10 - ‘To be exposed in an international context helps to understand whether the company direction is the right one’), and the role of external stakeholders. In line with a networked view of the firm, external stakeholder involvement is critical for both the assessment of the company’s efforts but also for its alignment with the business environment (e.g., Item 49 - ‘To collect feedback and align with external stakeholders to change’).

The cluster *Team Integration, Cohesion and Reach* contains thirteen items. It relates to the relevance of training and support offered to teams and its evolution in a transformation process (e.g., Item 6 - ‘To have training for team integration and teamwork’), but also the adoption of cross-functional teams and people rotation (e.g., Item 85 - ‘To create the conditions for working together across departments’). Along with efforts to increase transformation understanding, skills, and competencies internally goes the recognition that new people must share the company’s transformation attitude and new culture, willing to continuously improve and change (e.g., Item 59 - ‘To hire new people aligned with the right transformation attitude’).

Preparing Human Capital, Readiness and Trust is a fifteen-item cluster that captures another aspect of human capital. While the cluster *Team Integration, Cohesion and Reach* foster the holistic view of a company, here the emphasis is on employees and their role as autonomous actors. Participants convey the relevance of involving employees in a transformation process (e.g., Item 28 - ‘To start transformation first with people, i.e. ‘companies are of people’) and the need to raise ‘Awareness of today’s different ways of working’ (Item 15). Furthermore, to be ready for change and take on responsibility for the change to happen, employees need ‘to feel part of the transformation i.e., feel part of the solution’ (Item 36). The role of hierarchy - responsibility and delegation (e.g. Item 25 - ‘To understand what the people in leading position need to know and what to delegate’ - is a key topic. Employees need to be motivated to ‘explore new things in their work in line with a changing culture’ (Item 38) implying at the same time a new role of management and a different way to exercise leadership. The challenge of persuading middle management to embrace change emerges as a prominent obstacle during transformative phases (e.g., Item - 47 ‘To support middle management in understanding how its role, attitude, and behavior ought to change’). Consequently, a pivotal aspect of managing organizational transformation lies in providing robust support to middle management, facilitating their comprehension of forthcoming changes in roles and responsibilities (Girod, Birkinshaw, & Prange, 2023).

The cluster Culture Transformation and Outgrowth contains eleven items. Participants widely concur that organizational transformation necessitates a profound cultural shift. First, individuals must comprehend the rationale behind the change, the intended direction, and share its objective (e.g., Item 39 - 'To create a shared understanding within the company of why change is necessary e.g., benefits of change, resistance to change avoidance, feel the need to change, etc.'). Second, it is imperative to foster a change-prone culture at all levels that facilitates, supports, and aligns people with the change process. This involves the acceptance of potential errors as the workforce adapts to radically different operational modes and adheres to solutions proposed across various hierarchical levels (e.g., Item 77 - 'To perceive agile transformation as a radical change of mindset, more flexible and open'). It is crucial to recognize that cultural change extends beyond individual transformation; it must be accompanied by a radical shift in work methodologies, internal organizational structures, and organizational processes (Item 71 - 'To be ready to change the company's structure while transforming'; Item 62 - 'To be ready to change soft and hard factors e.g., culture, structure, processes').

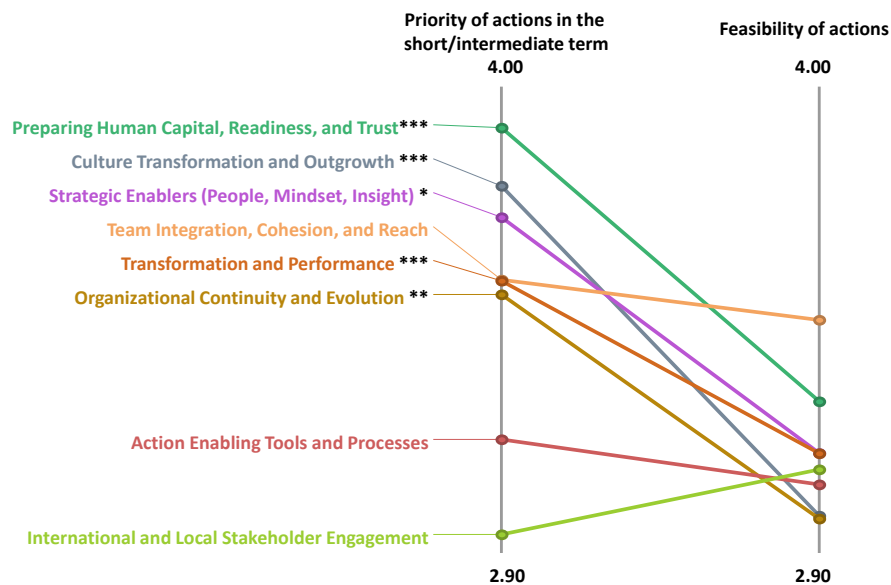

Organizational Continuity and Evolution is an eleven-item cluster. This cluster underscores the dynamic and evolving nature of the transformation journey, emphasizing the importance of adaptability and continual refinement in organizational practices. There is widespread consensus that a change process involves finding a balance among the actions to be implemented. This encompasses understanding how much emphasis to place on 'business as usual' as compared to the ongoing change and strategizing process (e.g. Item 44 - 'To find a balance between doing business and transforming at the same time'). The adoption of agile principles into organizational culture emerges as a powerful catalyst for driving collective efforts toward successful adaptation (Item 55 - 'To mobilize agile principles for culture change'). Furthermore, overcoming information bottlenecks in the minds of founders and managers is essential to unlocking innovation and streamlining decision-making processes (Item 68 - 'To break the information bottleneck that resides in the minds of founders and managers'). At the same time, preserving the benefits of smallness, such as information sharing and agile decision-making, remains critical during transformation efforts (Item 74 - 'To keep the advantage of smallness'). Moreover, individuals must recognize that an incremental and continuous transformation process is needed 'to facilitate the acceptance of change' (Item 52), so that the organization as a whole 'constantly learn while transforming/improving processes' (Item 73).

Transformation and Performance is a cluster composed of sixteen items that underscore the imperative to identify suitable performance metrics and create a common understanding (e.g. Item 24 - 'To develop an understanding of the relevant KPIs'). In turn, such standard processes are conducive to performance as they link back to goals and planning and, at the same time, enable corrective action. The transformation itself needs to be (re)active and responsive to changes but also the notion of performance as evidenced in Item 63 - 'To be reactive to changes in the environment, customer request, and regulation' - emphasizes a key goal and outcomes of agile transformation. Items in this cluster also evidence the need for a holistic view of transformation to achieve performance (e.g. Item 42 - 'To focus on several interrelated problems rather than on one problem at the time').

The pattern matches graph (Figure 2) shows estimates of the perceived priority and feasibility scales of the agile transformation clusters identified on the concept map. Pattern matches help identify how clusters are rated relative to the two scales examined (Likert-type five-point scales). Overall, the nonparametric Wilcoxon signed-rank test for matched data shows a statistical difference among participants between the priority and feasibility scales (p -value < 0.05).

Figure 2. Pattern Matches of the relative priority and feasibility of agile transformation actions†

† Ratings based on five-point Likert-type scales; Nonparametric Wilcoxon rank-order test for matched data pairs p -value < 0.05 between priority and feasibility scale ratings; *** p -value < 0.001; ** p -value < 0.002; * p -value < 0.05.

The results indicate that in agile transformation, participants have prioritized item sets pertaining to the clusters Preparing Human Capital, Readiness and Trust (rank 1); Culture Transformation and Outgrowth (rank 2); and Strategic Enablers (People, Mindset, Insight) (rank 3). It is interesting to note that participants perceive a high priority regarding cultural-related aspects yet the feasibility of such a softer dimension is not perceived as readily quickly achievable. As seen, the cluster ranked as a top priority, Preparing Human Capital, Readiness and Trust, ranks second in matters of feasibility. Looking for additional outcomes, the cluster Culture Transformation and Outgrowth ranks 7th which is much lower. Culture is typically slower to change (Grass, Backmann & Hoegl, 2020; Tronvoll et al. 2020), and thus, the lower feasibility of this dimension may not constitute an outright surprising result. This ranking relates perhaps to the fact that human capital internal training and support might need additional impetus that could be brought from external resources, whether through hires, stakeholder engagement, or additional structural-systemic alignment to reinforce a culture change.

However, Transformation and Performance is ranked 4th regarding its feasibility and is statistically different; and Organizational Continuity and Evolution is ranked 8th, that is last, for feasibility. The imbalance between the priority and feasibility for the latter cluster is perhaps associated with the tendency to prioritize major changes, despite feasibility hurdles that may arise from a shared understanding in the organization of the need to undertake major transformations. The priority and feasibility difference could arise from the belief that certain changes could have more significant and crucial impacts over time. Yet, when it comes to implementation, the readiness for concrete actions may not match their perceived immediate priority.

Surprisingly, Action Enabling Tools and Processes rank 7 and International and Local Stakeholder Engagement rank 8. External resources and know-how can support agility and change initiatives (Morton, 2023; Li et al., 2021), yet participants may undervalue stakeholders' contributions and the role of tools in easing implementation.

In today's business landscape, organizations must constantly evolve to remain competitive. Both external pressures and internal factors like company growth and shifting roles drive this transformation, highlighting its complex nature. To facilitate discussion, we have employed latent constructs to group the clusters into different regions of meaning (RM) for concept map interpretation (Kane & Trochim, 2007).

Figure 3. Concept map and regions of meaning (RM)

The RM Hard vs Soft Factors includes the cluster Action Enabling Tools and Processes. This region evidences tensions and the need for synergy for considering and measuring both hard and soft factors for an effective organizational transformation. Key performance indicators and their respective tools provide insights into an organization's transformation trajectory and outcome. However, organizations show a tendency to measure and emphasize primarily tangible and easily quantifiable results (Zairi, 2012).

Identifying appropriate proxies, continuous tracking, and incorporating these intangible aspects into the assessment is imperative (e.g., Item 46 - 'To customize tools and frameworks with the challenges to be addressed'). In addition to the ability to identify the 'what' and the 'how' to measure, it is also crucial to know the 'when' to measure during the

transformation process. This necessitates a balanced assessment encompassing both hard and soft factor metrics, that may challenge conventional ones. Thus, organizations are urged to look beyond 'surface-level' measures.

The *RM Autonomous vs Supportive Approach*, unites two clusters, emphasizing the pivotal role of individuals during the transformation process. As mentioned above, human capital and their involvement are considered essential and highly prioritized (e.g., Item 36 - 'To make people feel part of the transformation i.e., feel part of the solution').

Employee empowerment would necessitate a shift towards taking on responsibility and action at all hierarchical levels and ensure that people are prepared and able to accept such a shift (e.g., Item 66 - 'To motivate individuals and teams to take responsibility for change every step of the way'). Similarly, managerial levels need to comprehend the shift towards a supportive rather than authority-oriented approach (e.g., Item 47 - 'To support middle management in understanding how its role, attitude, and behaviour ought to change') - that transformational leadership is needed, and which structures and decision-making processes are requisite. Striking a balance involves defining explicit rules and roles while empowering teams to function autonomously through effective delegation (Grass, Backmann & Hoegl, 2020).

The *External vs Internal Stakeholder Involvement RM* includes one cluster. Examining the cluster in more detail, items describe two macro topics referring to stakeholders' involvement and international presence. The company's international presence items (e.g., Item 10 - 'To be exposed in an international context helps to understand whether the company direction is the right one'), claims that international exposure can be crucial for designing, assessing or potentially pivoting transformation efforts. Also, the literature emphasizes international exposure as a benefit to capture emerging trends and gain competitive advantage (Hagen et al., 2012). However, this cluster is not considered a priority for our participants. This could be because companies are already international and do not plan to further reinforce international activities in the short term. Yet, it would not be advisable to conclude that the international aspect is not relevant in the transformation context.

Furthermore, we can see that participants 'underestimate' the role of stakeholder engagement, both local and international, in the success of transformation. Although internal efforts are key, stakeholder engagement beyond company boundaries is needed to become and stay agile (Hagen et al., 2019). An explanation here may lie in the fact that stakeholder involvement may not occur in the early stages of a transformation. Extant literature on transformation claims that engaging stakeholders is a key pillar in the transformation (Morton, 2023; Li et al., 2021). However, this collective viewpoint among participants appears to challenge conventional expectations. While the transformation process inherently focuses on internal facets of the company, initiating and hoping to conclude a transformation without engaging external stakeholders can be considered unrealistic.

The *Incremental vs Radical Change RM* encompasses four clusters, namely Transformation and Performance, Organizational Continuity and Evolution, Strategic Enablers, and Cultural Transformation and Outgrowth. These clusters collectively pertain to the formulation of a transformative strategy within an organization. While recognizing the key role of individuals, teams and culture in the transformation, the need of changes to structure and operation models must be underscored when it comes to execution.

Research limitations. The limitations of this study are mainly the small sample size and the limitation to the generalization of the results. Although the number of participants in the focus group phase was more than sufficient to generate a good representation of the conceptual domain, a larger number of experts involved in the sorting and rating phase would have been preferable, as this allows for subgroup research. Indeed, the objective of the study is to provide an aggregated overview on the topic of agile transformation by considering the experiences and perspectives of all actors potentially involved in this transformation process.

At the same time, however, our choice and the number of participants in the sorting and rating phase do not allow us to further break down our results to have an intra-group view as well. The threshold for the size of the sorting and rating groups is between 20 and 25 to obtain valid results (Trochim, 1989). For this reason, in the future, it might be useful to collect more data to be able to observe not only the aggregate information but also to be able to compare the results between the different participants' sub-groups.

Managerial implications. This article addresses the implementation phase of agile transformation to broaden our comprehension of organizational and strategic agility. It makes a significant contribution to the existing body of knowledge on this topic by situating organizational renewal in today's dynamic business environment. In addition, the research has practical implications for managers in that it provides a solid foundation for the effective management of organizational change. It equips managers with the skills needed to lead and manage their organizations through important periods of change and adaptation, providing useful guidance and effective procedures.

Originality of the paper. This study aims to fill the gap in understanding the implementation side of agile transformation by illustrating the conceptualizations and perceptions of the challenges encountered in agile transformation trajectories and what solutions can be imagined to address them. In addition, the application of a mixed methodology, such as GCM, made it possible to estimate conceptual representations and measure perceptions about those representations. Indeed, it uses qualitative methods (e.g., brainstorming sessions and group interviews) and multivariate statistical methods to estimate the conceptualizations of groups of participants on a particular topic.

Participants (executives from large and established enterprises, scaleups, and stakeholders from the broader ecosystem) were purposively selected. In fact, large and established enterprises initiate the transformation process to become agile, while scaleups transform to remain agile. Finally, the stakeholder perspective allows unbiased information to be gathered.

Venture-Builders' Program Design and the creation of Scaleups

PAOLA BELINGHERI¹ CHRISTIAN LECHNER²

Abstract

The Venture-Building model has increasingly gained popularity in recent years across Europe as a promising model of innovation and entrepreneurship that can help mitigate the risks of startup creation and maximize the chances of success. In contrast with traditional business acceleration programs that support existing startups - who already have a founding team and a somewhat developed idea - with resources and networks, Venture-Builders are concerned with creating or building new startups starting only from an idea. They typically aim to create scalable companies or scaleups from the outset, drawing on the expertise of entrepreneurs-in-residence who have previous entrepreneurial successes under their belt.

As Venture-Builders have gained in popularity and success, a host of different actors, such as venture capitalists and business angels, universities, private companies and public sector institutions, have started to develop and implement their own Venture-Builders. These differ in various aspects, such as the infrastructure they make available to the startups, the degree of control they exercise, the extent to which they focus on specific sectors or technologies, where they seek ideas, how many ventures they build at the same time, and their relationship to funding sources. These aspects are, however, also connected with the ability of firms to scale and grow. Different Venture-Building models may thus be more, or less, suited to fulfilling the promise of creating scaleup companies, that exhibit sustainable growth, consistently over time.

Therefore, the paper attempts to shed light on the previously unexplored link between the features of the Venture Building process and the creation of scaleup companies.

Through a series of interviews conducted on Venture-Builders across Europe, set up by different types of actors, we create different archetypes of Venture-Builders and discuss their suitability to producing scaleups.

Key words: *Venture-building model; Startup Studio model; Venture-building process; Entrepreneurship; Scaleup*

Framing of the research. *The Venture-Building model has increasingly gained popularity in recent years across Europe and beyond. In contrast with traditional business acceleration programs, that support existing startups - that already have a founding team and an idea - with resources and networks, Venture-Builders are concerned with creating new startups from scratch, starting only from an idea (Kohler and Baumann, 2015; Pauwels et al., 2016). They often use a Factory metaphor to symbolize the churning out of startups - that they have "built" - consistently over time. The business ideas that are transformed into startups are either developed internally or sourced from external ideators. Startup execution is guided by a team of Entrepreneurs-in-Residence selected by the Venture-Builder that typically have had previous entrepreneurial or domain experience (i.e. marketing, sales, business design, talent acquisition, etc.) (Lesage, 2022). The startup stage follows rigorously outlined processes, where the Venture-Building team supervises and actively engages within the start-ups through thorough idea and solution validation steps to mitigate potential failures and de-risk the startup process (Sgambati, 2022). In addition, the newly minted startup teams are provided with resources and networking opportunities. In this way, Venture-Builders boast that they can create companies that will move more quickly from the startup to the scaleup phase.*

Venture-builders cultivate large talent pools that they can draw on to build capable teams for each startup idea. Building several ideas at a time in a repeatable fashion improves resource allocation for talent and capital, which can be redistributed between different startups as the projects advance and either fail, pivot, or continue. In addition to the team, which is an essential resource for any startup success, Venture-Builders also provide financial resources, attracting them both through their network and through their reputation in the funding (and founding) landscape. Finally, repeatable processes, that typically follow a lean startup methodology or a stage-gate process with multiple reviews, help to keep the startups on track towards achieving product-market fit (Kohler and Baumann, 2015).

Venture-builders are thus a promising model of innovation and entrepreneurship that can help mitigate the risks of startup creation and maximize the chances of success (Sgambati, 2022). Thanks to the success rates of this model, coupled with an increasing attention on entrepreneurship as a driver of economic growth, in the past years the creation of new

Venture Builders has risen rapidly, with 560 active venture-builders globally in 2021, expected to double to 1200 by 2023 (Alhokail et al., 2023, 2019). By 2019 Europe caught up with the USA in terms of the number of Venture Builders, and these had collectively raised as much Venture Capital as was available to traditional start-ups exiting accelerators (Alhokail et al., 2019).

This proliferation of Venture-Builders has created a large heterogeneity in the actors who are engaging in venture-building, which encompass venture capitalists, business angels, private companies, universities, and government institutions. In addition, the different Venture-Builders encompass a variety of design features that differ according to the vision of their founders. This has created a proliferation of models and terms, such as Startup Studio, Startup Factory, Company Builder, Venture Studio, Startup Foundry, and Startup Nursery (Lawrence et al., 2019). These different models may have an impact on the growth rates and the ambitions of start-ups that are born through the venture-Building model, thus impacting the number of scaleups that can emerge and thrive in the market.

Scaleups are defined as companies that achieve both high growth and wealth creation, and who thereby create a virtuous cycle where the wealth that is created can be used to fuel further growth. This happens thanks to a scalable business model, where scalability implies that the value proposition can be replicated such that revenues increase faster than costs (Monteiro, 2019). The transition from a startup to a scaleup is typically visible when the startup starts to harvest its first few clients, known as gaining market traction. At this stage, the more loosely structured startups need to acquire a more formal structuring that can support rapid growth (Picken, 2017).

Venture-Builders' Design

Examining Venture-Building models, Alhokail et al., (2019) identified six dimensions which can be used to describe different archetypes that have emerged over the years. These six dimensions are named: *The Guild*, *The Control*, *The Idea*, *The Funding*, *The Volume*, and *The Focus*.

The Guild: The Guild is the infrastructure package that Venture-Builders supply to their startup companies. It includes the *Entrepreneurs-in-residence*, *technological know-how*, *finance*, and *physical spaces*. The Guild may be shared horizontally between different startups in the portfolio to increase cost-effectiveness, or it can be distributed vertically for each business.

The Control: Venture-Builders have different rules governing the equity they hold in startups, according to their coaching intensity and required degree of control. Venture Builders who own significant amounts of equity, also have a higher control over their startups' decisions and may coach the startup for longer periods even beyond graduation from the Venture-Builder program itself. According to Alhokail et al., (2019), founders' equity stakes could range from 1% to 90%, which creates some very different conditions for the start-ups themselves.

The Focus: Venture-Builders can choose to operate across different sectors, covering a wide spectrum of technologies and markets, or they may operate vertically in a specific sector or on a specific technological solution (e.g. Artificial Intelligence or Deep Tech). The first approach is called the "Generalist" while the second is called "Specialist" (Alhokail et al., 2019). The first approach creates a critical mass of diversified investments that can mitigate overall risk, while the second approach benefits from a strong specialization of resources and know-how that leads to synergies that can be exploited by all startups in the program.

The Idea: Idea generation is a critical component of the Business Model of Startup Studios. Sourcing might be done externally or internally. External sourcing may take two forms: fostering external early-stage firms or scanning the market for the best venture to produce a Copycat (Sgambati, 2022). Internal idea sourcing, on the other hand, is a procedure that involves the commitment of Startup Studio specialized employees to generate new ideas.

The Volume: Startup studios can develop a few or many businesses concurrently. This is likely the most challenging choice to make when designing a Venture-Builder's Business Model. On the one hand, undertaking a small number of ventures, lessens the benefits and the synergies of the studio model, while on the other hand, overseeing too many initiatives concurrently degrades both the quality and number of human resources available to the guild for individual ventures. As a result, being able to balance resources and the number of ventures is a Key Success Factor for startup studios.

Funding: Startup studios can choose to finance their portfolio with their own resources or can choose external funding. Hybrid solutions are common, with external partners piggybacking onto the funding that the Venture-Builder makes available for the start-ups.

These dimensions are also very much related to startup growth once it reaches the market and may result in very different success rates in creating companies that rapidly advance towards the scaleup stage. This paper thus maps the different models of Venture-Builders in Europe and relates their model to the effective capability of building scaleup companies.

Purpose of the paper. Literature has emphasized how, from the outset, Venture-Builders aim to create startups with scalable business models. Indeed, Venture-Builders themselves also broadcast the objective of creating scale-ups rather than traditional start-ups. A comparison of the top 21 companies to emerge from Venture-Builders with the top 21 companies that graduated from acceleration programs revealed that companies from accelerators raise 105% more money, but companies from Venture-Builders have a 26% higher growth (Szigeti, 2016). This would imply that Venture-Builders are indeed more adapted to creating scale-ups. However, an analysis on outliers cannot be considered representative of the overall success rate of Venture-Building, which, similarly to startup creation, follows a power-law distribution with a very long tail of unsuccessful cases and a few very successful ones (Clauzet et al., 2009). We contend that there are design features of Venture-Builders that are more or less effective in producing scaleup companies and attempt to investigate this further.

Methodology. *The research is based on multiple case studies through desk research of 32 Venture-Builders in Germany, The Netherlands, The UK and Spain, and interviews conducted between 2023 and 2024 of 6 venture-builders in Italy and Greece, where we used the owners and managers of the venture-building programs as key informants. The desk research and interviews enabled us to explore the different components of the actors' Venture-Building model following Szigeti (2016). From the individual cases, we derived different archetypical models of venture-builders. Considering differing contexts, the case conclusions develop propositions that express which of these models are more suited to producing scaleups rather than startups, presenting some case studies to illustrate the theory.*

Results

Venture-Building Models

The following descriptions were derived from the interviews and the desk research, and they concern different venture-building models according to the different types of actors that created the Venture-Builders. The Venture-Builders used to create these models are spread across Europe, both in highly innovative and low innovating regions. They typically concern high-tech industries and digital technologies (Daunfeldt et al., 2016), although there are also some generalists that have no particular focus.

Universities

Guild: Universities tend to compose teams from internal affiliates only (students, researchers, faculty, alumni), without providing external or expert CEOs and other key staff.

Control: Universities typically hold no control over the startups they create through venture-building

Idea: Idea generation is generally internal and is deputized to the students

Funding: Universities typically provide no funding for the startups, beyond some small awards (sometimes from external partners).

Volume: Universities tend to produce many businesses concurrently, to accommodate all the students with an entrepreneurial vocation. Out of all the groups built, there is an award at the end for a handful of the best ideas and executions.

Focus: Universities tend to be generalists in their focus, in line with their vocation as multidisciplinary institutions, but mirroring the disciplinary areas where their research efforts are present or strong.

Additional information: Universities often create these programs as part of their third mission. The key metrics they mentioned were the number of startups created, the number of students participating in the program, and the market cap of all the startups created over time.

Institutions

Guild: Institutions rely on external participants to form teams, without providing key staff

Control: Institutions typically hold no control over the startups they support

Idea: Idea generation is typically external and is entirely up to the startups

Funding: Institutions may provide funding, but it's generally limited to seed capital or capital to sustain the acceleration phase.

Volume: Institutions tend to produce several businesses concurrently

Focus: Institutions tend to be generalist, while focusing on broad issues for the municipality or region where they are embedded (e.g. smart cities, transportation, tourism)

Additional information: Institutions reported wanting to accelerate local innovation and inject new technologies into the current ecosystem as their main motivation for creating a venture-builder. They rely on partnerships with key actors from the local ecosystem to create the entrepreneurial ecosystem.

Corporations

Guild: Corporations tend to provide all the staff internally from their company

Control: Corporations tend to maintain at least partial control over the startups they create through venture-building

Idea: Ideas are created internally by employees and managers

Funding: Corporations typically provide seed funding for the startups and further funding for a subset.

Volume: Corporations typically focus on small to medium volumes

Focus: Corporations tend to have a more specialized outlook with a focus on their key markets and technological areas

Additional information: Corporations are looking to capitalize on internal under-used knowledge to open up new markets and new revenue streams. They often rely on external partners for the Venture-building program at least at the

outset, because specialized knowledge is necessary to create a successful venture-builder. They fund the venture-building programs themselves.

Venture-Capitalists and Angel Investors (VCs)

Guild: VCs often provide the CEO and other key personnel in the venture. They typically look for professionals or researchers with technical expertise who need the complementary management expertise. They either personally participate in the ventures or look for capable managers within their personal network.

Control: VCs take a percentage of control of the final idea, to sustain their business model.

Idea: Ideas are typically scouted from the external landscape, both the professional world and the research and university sector.

Funding: VCs may provide their own funding to start-ups and seek to attract external funding from other VCs. In this case, credibility of the venture-building staff is critical to attract and retain funding sources. Credibility implies having already created successful businesses in the sectors they focus on.

Volume: VCs typically go for very low volumes, as the venture-building staff is personally invested in each venture and is part of the founding team.

Focus: VCs are often sector-specific and pursue a sectoral or even more narrow focus, where they are the most knowledgeable and credible.

Additional information: VCs and Angel Investors treat venture-building as a business, in which they obtain returns by providing all the building blocks to sustain great ideas. Their credibility is thus on the line with each new startup. They use their own funding, however, may also resort to external investors such as other VCs, banks, and private companies.

Venture-Building Models and Scaleups

Literature has examined several conditions that are important in the creation of scaleups. First, when companies reach the scaleup phase, they have a significant increase in the resources they need to fuel their growth. These resources must come from the broader entrepreneurial ecosystem in which the company is embedded, to which they typically get access through the Venture-Builder itself and the networks in which it is embedded (Mohr et al., 2014). In addition, the Board of directors and the managers of such a scaleup also play a role in this search for resources, through their personal networks but also increase the ability of scaleups to capitalize on the resources they receive (Zahra et al., 2009). Scaleups also often need human resources, that must be hired and trained. In this context, both the networks of the startups but also the mentorship and guidance from top management can be of great importance in this process. This is even more important in the event that the startups are in high-tech sectors and need advanced expertise for their further development, which seems to be often the case (Daunfeldt et al., 2016).

From this point of view, the different Venture-Building models have distinct advantages. On one hand, the more specialized models such as those of VCs/Angels and Corporations have in-depth domain knowledge and networks of human resources they can tap into, as well as providing specialized founders and managers through the guild. In addition, they can usually mobilize more capital. Universities can mobilize specialized human resources but have less to offer in terms of entrepreneurial experience and access to funding. Public institutions rely on external actors to mobilize all necessary resources, and thus seem to be in a weaker position to provide these essential assets.

Literature also focuses on the amount of control that the scaleup founders have over the company. In particular, control is expressed as a currency that may be exchanged for external resources including funding (Wasserman, 2017). Thus, the more the scaleups are dependent on external resources, the more they will have to relinquish control over their firm in exchange for these. Venture-Builders who retain a large amount of control over their startups, such as the VC/Angel models and the corporate models, may in future hamper the businesses' ability to acquire precious resources at the scaleup phase. The university and public institution model, by hardly taking any control, may leave more flexibility to the startups in this sense.

Finally, the power-law distribution would imply that creating scaleups is also a numbers game. Therefore, those Venture-builders who create many tens of startups at the same time, i.e. typically those of universities, have higher probabilities of producing scalable businesses that ultimately see above-average returns.

Research limitations. The paper is based on an analysis of venture-builders in Europe. This is original w.r.t previous literature which has focused more on the US market, however European conditions for entrepreneurship are significantly different than in other global regions and could give rise to Venture-building models that are not easily replicable elsewhere. There are also country-level indicators that influence the dynamism and thus the potential for producing scaleups of the business environment (Bravo-Biosca et al., 2016), and these could in future be factored into the discussion.

Managerial implications. The results of this research could help inform Venture Capitalists to understand the potential returns they could receive by backing a Venture-Builder. It could help innovators who are considering pursuing the Venture-Building route or the Accelerator route to understand tradeoffs between the support they are receiving and the capital they are relinquishing. Finally, it could support policymakers who are considering promoting or supporting these types of initiatives as part of regional and national innovation strategies.

Originality of the paper. The paper attempts to shed light on the previously unexplored link between Venture Studio Design and the creation of scaleup companies. As the Venture Builders or Venture Studio model becomes more popular, different actors are experimenting with different designs according to their specific roles, objectives and experiences, we assess on a theoretical basis which of these models may be more suited to producing scaleups.

Entrepreneurial Ecosystems: exploring the Italian Tech Scaleups scenario

SERENA VALENTE¹ ALESSIA PISONI²

Abstract

The ecosystem approach has increasingly attracted the interest of management scholars starting from Moore's contribution of 1993. Ecosystem literature has developed over time, differentiating ecosystems on the basis of attributes and goals. Among these, entrepreneurial ecosystems (EE) have recently emerged as a novel domain of research.

After the seminal work of Cohen (2006), EE research has been complemented by an increasing number of contributions. Based on extant literature reviews (Wurth et al., 2022), it took almost a decade for research focused on EE to flourish. Contributions span from theoretical work aimed at understanding what ecosystems are (Isenberg, 2010; Mason and Brown, 2014; Stam, 2015; Audretsch et al., 2019), which conceptual boundaries and goals they have (Stam, 2015; Stam and Spigel, 2016; Spigel, 2017; Cobben et al., 2022), how complementarities and interdependencies are managed (Feld, 2012; Stam, 2015; Spigel and Harrison, 2018), to empirical research aimed mainly at highlighting level and typologies of output (Brown and Mason, 2017; Audretsch et al., 2019; Stam and van de Ven, 2021).

A recently published systematic analysis of the EE literature stress the importance of "re-orienting research on entrepreneurship and economic development toward productive entrepreneurship" (Wurth et al., 2022: 731). The concept of productive entrepreneurship is sought to capture both EE output (entrepreneurship) and outcome (aggregate value creation). As stated by Stam and van de Ven (2021: 817), "there are no perfect measures of either entrepreneurship or aggregate value creation". In this respect, understanding the dimensions and indicators to be used to study productive entrepreneurship in this rapidly emerging research field represents a crucial issue (Cobben et al., 2022).

On this basis, we aim at contributing to this research need by focusing on scaleups as a proxy of productive entrepreneurship. Leveraging the privileged access to the Mind the Bridge proprietary database, we focus the analysis on the Italian tech scaleups scenario (Mind the Bridge Tech Scaleup Italy Report, 2023). We aim to provide an overview of its main characteristics with descriptive statistics and statistical analysis, by thoroughly investigating the scaleups' economic-financial performance, innovation performance, and markets served. Variables related to the founding team characteristics, such as founders' background and evolution over time are also considered. We also aim to identify common growth patterns both at national and regional level and their evolution over time.

Future research implies extending the study at the international level, with a preliminary focus on the European scaleup scenario.

At the time of writing the study is still in progress.

Key words: *entrepreneurship; entrepreneurial ecosystems; productive entrepreneurship; scaleup.*

Framing of the research. *Besides the fact that entrepreneurial ecosystems (EEs) have gained increasing popularity, a common definition agreed upon by researchers and practitioners does not yet exist (Stam and van de Ven, 2021; Wurth et al., 2022). The EE concept has two components. On the one hand, "entrepreneurial" refers to "a process in which opportunities for creating new goods and services are explored, evaluated and exploited" (Stam and van de Ven, 2021: 811, based on Schumpeter, 1934; Shane and Venkataraman, 2000). On the other hand, the "ecosystem" component is a transdisciplinary concept arising from the biology field (Stam and van de Ven, 2021; Theodoraki et al., 2022) characterized by three core features: co-evolution, mutualistic interdependence and a complex system of interactions among actors. Accordingly, EEs are defined as "a set of interdependent actors and factors" (Stam, 2015: 1765). These actors co-evolve, making the ecosystem of actors a complex interactive system (Stam and van de Ven, 2021).*

EEs consist of different typologies of actors, which can be traced back to the following categories: governmental organizations, financial actors as venture capitalists and investors, universities and support organizations such as incubators and accelerators, and independent orchestrators as individual entrepreneurs (Cobben et al., 2022). Each actor has a prominent role, depending on the stage of development of the specific EE (Guéneau et al., 2023). According

¹ University of Insubria
e-mail: svalente@uninsubria.it

² University of Insubria
e-mail: alessia.pisoni@uninsubria.it

to Auerswald and Dani (2017), there are four main stages of EE development, embedded in an adaptive life cycle, as ecosystems are dynamic and constantly adapt their structures. The development of EEs begins with the exploitation phase and matures into the conservation phase. At this point, the structure of the ecosystem becomes denser and more interconnected, i.e., more rigid. If a strong shock occurs, EEs enter the release phase, which is immediately followed by a reorganization phase.

Actors within an EE have two different perspectives and two main objectives: at the micro level, each individual ecosystem actor behaves in a way that maximizes its own economic growth, while at the macro level, each ecosystem actor seeks to maximize the economic development of the entire ecosystem, be it a nation, region or local area (Acs et al., 2018; Cobben et al., 2022). Both levels influence each other, as ecosystem actors are interdependent.

Actors and factors organized within EEs enable productive entrepreneurship (Stam and Spigel, 2016; Stam, 2015). Any entrepreneurial initiative is considered as productive when its net effect on productivity is positive, i.e., if it contributes to increase the overall output of the economy or improves its ability to produce more goods and services, either directly or indirectly (Baumol, 1993). Productive entrepreneurship contributes to economic growth by fostering innovation and technological improvements, the accumulation of human and entrepreneurial capital, and the replication of successful products and process innovations (Minniti et al., 2023).

According to Stam and van de Ven (2021: 817), an “entrepreneurial ecosystem is said to produce entrepreneurship as an output and ultimately aggregate value as an outcome”. However, “there are no perfect measures of either entrepreneurship or aggregate value creation”. According to Wurth et al. (2022: 731) the EE concept can contribute to policy making, by “re-orient[ing] research on entrepreneurship and economic development toward productive entrepreneurship”. In this respect, the concept of productive entrepreneurship (Stam, 2015) is sought to capture both EE output (entrepreneurship) and outcome (aggregate value creation).

Based on the evidence that startups and scaleups are seen as sources of innovation, productivity growth and employment (Mason and Brown, 2014; Autio et al., 2018), productive entrepreneurship is often narrowed down to high-growth entrepreneurship (Autio and Ranniko, 2016; Wurth et al., 2022). Accordingly, a high-quality EE is more likely to produce high-quality entrepreneurship (Stam and van de Ven, 2021; Minniti et al., 2023).

To date, empirical studies have proxied productive entrepreneurship with either innovative new firms/startups (Leendertse et al., 2022), high-growth firms (Stam and van de Ven, 2021), gazelles (Stam, 2018) and unicorns (Leendertse et al., 2022). Nevertheless, additional empirical research needs to be done (Minniti et al., 2023).

Purpose of the paper. The study attempts to investigate the performance/quality of entrepreneurial ecosystems, by specifically proxying productive entrepreneurship with scaleups. Despite the importance of “scaling-up” in contributing to improve national competitiveness (Audretsch and Acs, 1994; Gilbert et al., 2006; Audretsch et al., 2015; Mind the Bridge, 2019; Piaskowska et al., 2021), the definition of scaleup is still controversial (Coviello, 2019) and lacks of a common understanding (Pisoni and Onetti, 2023). Coviello (2019) argues that too often scaleups have been confused with “high-growth firms” (Demir et al., 2017) and that “scaling is not just about high-growth” (Tippmann et al., 2018; Coviello, 2019). Besides the definition, scholars agree on the fact that “scalability” is to be considered as a crucial aspect (Autio, 2016). For the purpose of our research, we adopt the definition of scaleup as “a development-stage business, specific to high technology markets, that is looking at growth in terms of market access, revenues, and number of employees, adding value by identifying and realizing win-win opportunities for collaboration with established companies” (Onetti, 2014; Startup Europe Partnership (SEP), 2015; Autio, 2016). Specifically, Startup Europe suggests a tangible definition for a scaleup: a new venture that has attracted 1 Million USD or more of venture capital funding. Besides the ongoing debate on the definition of scaleups, it is acknowledged the role they play in introducing technologies into the market (Coutu, 2014). Also, for their potentials to disrupt innovation- and entrepreneurial ecosystems in which they are embedded (Marcon and Ribeiro, 2021; Autio et al., 2018), they have been increasingly attracting the interest of scholars, practitioners and policymakers (Coutu, 2014; Onetti, 2014; SEP, 2015; Autio, 2016; Autio et al., 2018).

Methodology. To contribute to the study of the performance of EEs and leveraging the privileged access to the Mind the Bridge³ proprietary database, we focus the analysis on the Italian tech scaleup scenario with the aim to understand which are scaleups’ characteristics (either at the firm and team-levels), their growth path and the relationships established to conduct their innovative activities. The Italian context is particularly noteworthy for our analysis since it is currently experiencing a new big wave of productive entrepreneurship thanks to the Italian policy maker attention (Girauda, 2019; Matricano, 2020, 2022; Cavallo et al., 2021; Biancalani et al., 2022). By issuing the “Italian Startup Act”, the Italian policy maker aimed to provide a comprehensive legislative framework to foster the creation and growth of its entrepreneurial ecosystem, by providing benefits to all those entrepreneurial activities recognized as innovative and therefore productive (Italian Startup Act, 2019).

By thoroughly investigating the Italian scaleup scenario, we aim to provide an overview of its main characteristics with descriptive statistics and statistical analysis. With this purpose, we are investigating the scaleups’ economic-financial performance (either considering their fundraising path and their growth in terms of turnover, employees and

³ Mind the Bridge is a global organization that provides innovation advisory services for corporates and startups. In 2014, Mind the Bridge has been selected by the European Commission to lead Startup Europe Partnership (SEP). Established in January 2014 at the World Economic Forum in Davos, SEP is a Startup Europe initiative dedicated to support the growth and sustainability of European startups able to compete and raise funds internationally. Based on its proprietary database, Mind the Bridge regularly produce reports with the goal of sharing insights and data about startup/scaleup ecosystems in order to give relevant parties a macro overview of the current landscape (<https://mindthebridge.com/research/>).

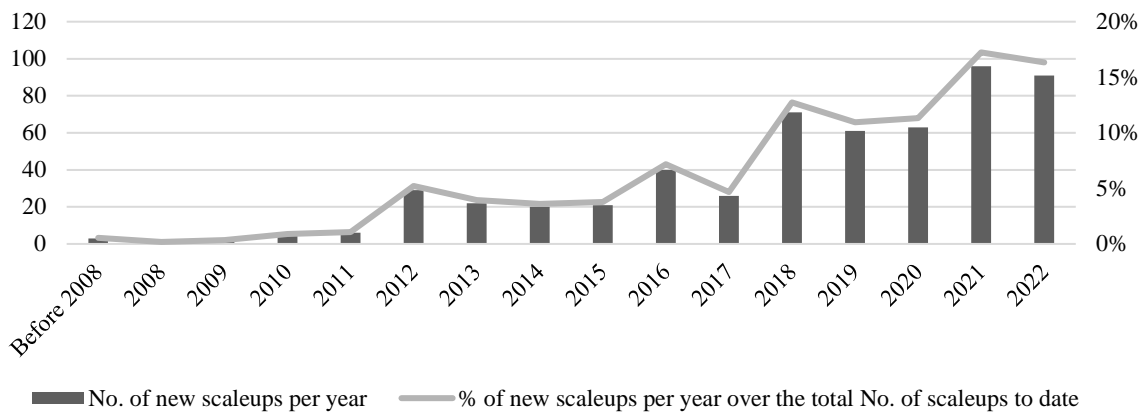

profitability margins), innovation performance (in terms of R&D, collaborations with universities/incubators etc., and the use of digital technologies), and markets served (in terms of customer segment and geographic scope). Variables related to the founding team characteristics, such as founders' background and evolution over time are also considered.

In doing so, we also aim to identify common growth patterns both at national and regional level and their evolution over time. Furthermore, the analysis of the Italian scaleup scenario represents the basis of future research extending this study at the international level, with a preliminary focus on the European scaleup scenario.

Results. At the time of writing, research is still ongoing. A preliminary analysis by focusing on the overall population of Italian tech scaleups has been conducted. As of December 2022, Italy is home to 557 tech scaleups (Mind the Bridge Tech Scaleup Italy Report, 2023).

Figure 1 shows the distribution of Italian tech scaleups by year. Prior to 2018, the Italian scaleup scenario was relatively small, with an average of approximately 20 new scaleups per year. However, from 2018 to 2020, Italy experienced significant growth, with an average of 65 new scaleups per year. In the last two years (2021-2022), the Italian scaleup scenario has continued to expand, producing nearly 100 new scaleups annually.

Figure 1: Distribution of Italian tech scaleups by year of establishment

Source: Personal elaboration based on MtB data (2023)

A tech scaleup is a company operating in the tech and digital industries (excluding biotech, life sciences, and pharma, as well as semiconductor industry verticals); founded in the new millennium, have had at least one funding event since 2010, and have raised more than 1 Mio USD in funding (Mind the Bridge, 2023). The concentration of Italian tech scaleups is significant in a few strategic industry verticals (Figure 2). The vast majority of scaleups focus in Healthtech, in Ecommerce, in Business & Productivity Software, and in Advertising. The 'Other' column groups industry verticals with scaleup frequencies lower than 10 (e.g., Aerospace, Agritech, Autotech, Fintech, Gaming, HR Tech, Logistics, Smart City/Home, etc.).

Figure 2: Italian tech scaleups industry specialization

Source: Personal elaboration based on MtB data (2023)

Italian tech scaleups have raised over 7 Bio USD. The vast majority of scaleups have had so far mainly 1-3 funding

event(s), raising on avg. 9 Mio USD. Sources of funding can vary considerably. They may include venture capital investments, which can come from private funds, public-supported equity funding vehicles, and corporates. Scaleups may opt also to go public - and retrieve funding from the stock market through an Initial Public Offering (IPO) - or issue cryptocurrencies in exchange for legal tender, through an Initial Coin Offering (ICO). Data show how Venture Capital (VC) is the main source of funding for Italian scaleups; while ICOs are uncommon, IPOs are increasingly considered as a viable option for scaleups to raise growth capital (i.e., 11% of total funding made available to Italian scaleups comes from the stock market). It is also worth noting how scaleups that opt for an IPO, rarely also raise VC money. Specifically, only 20% of scaleups that go public had previous VC rounds of financing (having raised on avg. 4.5 Mio USD); intuitively the vast majority of capital was raised during the IPO (on avg. 16 Mio USD, with a huge variability among). Thus, signaling how the IPO has been properly planned to secure funds to support the scaleup growth path.

It is also worth analyzing the distribution of the total funding over the lifespan of the scaleup. Intuitively, it is way different to have only one financing round when the scaleup is young compared to having only one financing round as a mature scaleup. Considering the scaleup older than 10 years (those who have experienced some history, and survived the lack of funding characterizing the Italian private equity market), we can draw some interesting considerations. The oldest among the scaleups considered had a limited number of funding events, but raised larger amount of funding, who allowed them to survive longer. The youngest (among the same considered scaleups) had more funding events, but relatively smaller in terms of amount raised, thus signaling a more fragmented fundraising path.

Results are in line with the so-called “dual companies” phenomenon (Onetti and Pisoni, 2021), i.e. scaleups that move their HQs abroad, while keeping relevant operations in their country of origin (usually R&D and product development). The main reason to relocate the HQs was to get access to capital, mainly later stage funding. Dual companies appear to be less widespread in countries where the venture capital industry is more developed, while it is a more frequent phenomenon in new emerging entrepreneurial/startup ecosystems (Onetti, 2017). Although a lot of progress has been made with regards to early-stage financing, the phenomenon is evolving in parallel with the growth of the venture capital industry in various regions and countries and needs to be monitored closely (Onetti and Pisoni, 2021)

The Italian scaleup landscape is mainly made of small companies. Firms can be classified based on their size, with the number of employees being one of the most common criteria (OECD, 2024). This allows for the identification of four size categories and corresponding company size definitions: micro, small, medium, and large enterprises⁴. As shown in Table 1, to date 85% of Italian tech scaleups are micro and small enterprises. Medium-sized enterprises account for only around 13%, while large enterprises account for just 2%.

Table 1: Italian tech scaleups by size (no. of employees)

No. of employees*	Size category	Percentage of scaleups (on the overall amount considered) per size category
0 - 4	Micro enterprise	25%
5 - 9	Micro enterprise	15%
10 - 19	Small enterprise	22%
20 - 49	Small enterprise	23%
50 - 249	Medium enterprise	13%
More than 250	Large enterprise	2%

Source: Personal elaboration based on MtB data (2023)

Note*: last year available

When evaluating the performance of Italian tech scaleups, we use the total sales. Table 2 shows that most scaleups have a turnover between 0 and 5 Mio euros, with peaks for those with a turnover between 0 and 100,000 euros. It is also worth noting a promising growth path for scaleups with a turnover higher than 2 Mio euros. Data show an interesting 11% of Italian tech scaleups with a revenue size between 10 and 50 Mio euros. However, only the 3% of overall Italian tech scaleups have a turnover exceeding 50 Mio euros.

We can thus conclude that the vast majority of Italian scaleups are still quite small (Table 1 and 2).

Table 2: Italian tech scaleups by total sales

Scaleups' turnover (thousands euros)*	Percentage of scaleups (on the overall amount considered) per category of turnover
0-100	19%
100.001-500	15%
500.001-1,000	12%
1,000.001-2,000	14%
2,000.001-5,000	17%
5,000.001-10,000	9%
10,000.001-50,000	11%
More than 50,000,001	3%

Source: Personal elaboration based on MtB data (2023)

⁴ A micro enterprise is a company with fewer than 10 employees, while a small enterprise has between 10 and 50 employees. A medium enterprise has between 50 and 250 employees, and a large enterprise employs more than 250 people.

Note*: last year available

By considering data at geographical level, it appears that scaleups tend to cluster around major financial centers. Accordingly, Figure 3 shows that the majority of Italian tech scaleups are headquartered in Milan, accounting for approximately 45% of the total population. A significant percentage of scaleups are located in various cities across the Italian peninsula. Specifically, 10% are in Rome, 5% in Turin, and approximately 2% in Cagliari, Naples, Bologna, Florence, and Modena. In Southern Italy three scaleup hubs are emerging around Naples, Cagliari and Bari. In Sicily, scaleups are concentrated around Palermo and Catania.

Figure 3: Italian tech scaleups geographic concentration

Source: Personal elaboration based on MtB data (2023)

It is also worth noting that some Italian local ecosystems are trying to leverage outside-in and inside-out initiatives to fuel their growth at scale. Examples are the innovation antennas in Silicon Valley by Sardinia Region (ASPAL) and Emilia-Romagna (ART-ER) as well as the ORA! initiative - the first territorial Venture Client scheme deployed in the broader Ravenna oil & gas, chemistry and waste management cluster.

As anticipated in the abstract, at the time of writing research is still ongoing. Variables related to the founding team characteristics, such as founders' background and evolution over time will be also considered in relation to scaleup characteristics and performance. Common growth patterns both at national and regional level and their evolution over time will also be highlighted.

Research limitations. Research is still ongoing. The focus on the Italian tech scaleup scenario might limit the generalizability of findings to other contexts or industries. Factors specific to the Italian ecosystem may not be applicable to other regions or sectors.

Managerial implications. Our study aims to improve the understanding of entrepreneurial ecosystems by using a data-driven approach that focuses on scaleups as their productive outcome. This study sets the stage for advancing our understanding of the role of scaleups in entrepreneurial ecosystems. In this regard, we focus on the underexplored topic of productive entrepreneurship in line with the research need highlighted by Wurth et al. (2022), i.e. to reorient entrepreneurship research towards productive entrepreneurship, and we stimulate the ongoing debate among practitioners and policymakers about scaleups and entrepreneurial ecosystems' policies development.

Originality of the paper. The novelty of this study lies in employing scaleups as a proxy of productive entrepreneurship in entrepreneurial ecosystems. By analyzing data from the Italian tech scaleup scenario, the study aims at providing empirical evidence on the characteristics, growth trajectories, and performance of scaleups within a specific context, addressing the call for more empirical evidence on EEs. Besides, being at an early stage of development, the study aims at providing useful insights for policymakers and practitioners.

Innovazione e imprenditorialità femminile nelle PMI: un'analisi fuzzy dei driver della performance

ANTENOZIO LUDOVICA¹ DI BERARDINO DANIELA²

Abstract

Il presente studio si propone di esaminare quali combinazioni di attività e risorse promotrici dell'innovazione consentono di conseguire alte performance finanziarie nelle PMI innovative, discriminando tra PMI a conduzione femminile ed altre. Nel crescente dibattito sulla trasformazione delle PMI, l'innovazione riveste un ruolo sempre più centrale nello sviluppo di tali imprese le quali, contribuiscono in modo significativo alla crescita economica e alla competitività nazionale. Le attività innovative interne e le risorse riconducibili al capitale umano, ai brevetti e alla R&S vengono considerate come driver di innovazione capaci di influenzare le performance aziendali, ma non sempre garantiscono un impatto positivo nel lungo termine né una relazione lineare. Utilizzando una metodologia di analisi qualitativa comparativa del tipo fuzzy-set (fs-QCA), innovativa e adeguata allo studio di fenomeni caratterizzati da incertezza, i risultati preliminari dello studio suggeriscono che diverse combinazioni di investimenti in R&S, capitale umano qualificato e proprietà intellettuale, possono determinare una performance positiva per le PMI innovative, mentre l'imprenditorialità femminile non assume un ruolo preponderante e discriminante. Questo studio contribuisce alla comprensione della relazione complessa tra innovazione, imprenditorialità femminile e performance nelle PMI e offre importanti implicazioni manageriali e teoriche.

Key words: *innovazione, PMI innovative, fs-QCA, genere, performance, R&S, imprenditorialità femminile, brevetti, capitale umano*

Inquadramento della ricerca. *L'innovazione sta assumendo oggi un forte interesse come fattore guida della crescita delle imprese (Arcuri et al., 2023; Audretsch, Coad, et al., 2014), e svolge un ruolo cruciale nel ridisegnare il vantaggio competitivo delle piccole e medie imprese (PMI) (Arcuri et al., 2023; Montani et al., 2023), che, da una lato, si caratterizzano per la scarsità di mezzi (Costa et al., 2023; Vagnani & Proietti, 2023) e risorse (Antenzio & Di Berardino, 2023; Costa et al., 2023), dall'altro contribuiscono alla crescita economica e alla competitività nazionale (Albis Salas et al., 2023; Audretsch, 2002; Audretsch et al., 2023; Vagnani & Proietti, 2023) rappresentando il 99% delle imprese europee nella maggior parte dei Paesi (OECD, 2021). L'innovazione diventa per le PMI un requisito imprenditoriale necessario per il conseguimento di un solido vantaggio competitivo, determinando solitamente la creazione di una proposta di valore unica e distintiva (Schumpeter, 1934), che a sua volta consente alla PMI di agire come motore per la competitività nazionale (Albis Salas et al., 2023; Antenzio et al., 2023; Audretsch, 2002). Pertanto, le PMI si trovano spesso a reinventare le proprie attività e a ridefinire le proprie risorse (Albis Salas et al., 2023; Antenzio et al., 2023), per alimentare nel continuo l'innovazione e rispondere adeguatamente ai cambiamenti tecnologici (Montani et al., 2023).*

Le attività interne di promozione dell'innovazione risultano essere dei driver che consentono di ottenere risultati ad alta performance anche nelle PMI (Arcuri et al., 2023; Matricano, 2023). Adottando la lente teorica della resource-based view, si rileva che gli investimenti in ricerca e sviluppo (R&S) costituiscono risorse interne strategicamente rilevanti, che agiscono come driver dell'innovazione (Albis Salas et al., 2023; Arcuri et al., 2023) e che favoriscono l'ottimizzazione dei processi, determinando un incremento della produttività delle PMI (Albis Salas et al., 2023). Tuttavia, atteso che tali risultati positivi non sempre si rivelano o si manifestano nel lungo termine, gli investimenti in R&S possono drenare lungamente le risorse finanziarie nelle PMI, agendo quindi negativamente sulla complessiva efficienza produttiva e sulla performance finanziaria e reddituale (Lee et al., 2019). Pertanto, gli investimenti in R&S possono non essere sufficienti per promuovere elevate performance, né la loro relazione con la sopravvivenza aziendale si qualifica sempre come lineare (Ugur et al., 2016). Per questi motivi è opportuno considerare altri indicatori di attività generatrici dell'innovazione e promotrici della performance, come la presenza di risorse uniche ed inimitabili tutelate da diritti di proprietà intellettuale (Audretsch, Segarra, et al., 2014). In letteratura tale variabile è utilizzata come parametro del grado di originalità e unicità della proposta di valore (Athreye et al., 2021) e la sua "esclusività" tutelata legalmente la rende una risorsa rilevante per il duraturo sviluppo della PMI (Matricano, 2023). Tuttavia, i brevetti di per sé, pur

² Università "G. d'Annunzio" Chieti - Pescara
e-mail: daniela.diberardino@unich.it

costituendo una condizione necessaria per qualificare una PMI come innovativa, necessita della combinazione di altri processi e risorse per condurre la PMI ad elevate performance e, sovente, la redditività generata da tale investimento tarda a manifestarsi (Tagliatalata & Barontini, 2024). Alcuni studi evidenziano come misurazioni quantitative basate esclusivamente sul numero di brevetti non sono sufficienti per valutare adeguatamente l'impatto sulla performance delle PMI (Burrone, 2005; Macdonald, 2004), essendo necessaria una variabile qualitativa che descriva il tipo di innovazione tutelata (Agostini et al., 2015). Inoltre, appare incerta la direzione della relazione tra brevetti e performance finanziaria della PMI: taluni autori rilevano la presenza di relazioni positive (Agostini et al., 2015; Maresch et al., 2016), altri rilevazione relazioni negative (Power & Reid, 2021), taluni nessuna associazione (Griliches et al., 1991).

In letteratura anche il capitale umano emerge come un fattore chiave per il vantaggio competitivo delle PMI (Kiefer et al., 2022) e per la redditività aziendale (Xu & Li, 2019), impattando positivamente sugli utili e sull'efficienza operativa delle imprese (Kiefer et al., 2022; Xu & Li, 2019). Tuttavia, risultati contrastanti nell'interazione tra innovazione e performance nelle PMI sono stati riscontrati in alcuni studi. Sebbene studi manageriali riconoscano all'innovazione una valenza propulsiva, per elevare la capacità competitiva (Audretsch, Coad, et al., 2014; Porter, 1980), sviluppare capacità dinamiche (Eisenhardt & Martin, 2000) e, favorire la sopravvivenza delle imprese (Audretsch et al., 2020), specialmente nelle PMI (Arcuri et al., 2023), si rileva, d'altro canto, che il processo di innovazione può portare ad elevati tassi di insuccesso, compromettendo la performance e aumentando il profilo di rischio dell'impresa (Li & Atuahene-Gima, 2001; Scherer & Harhoff, 2000). Lo studio delle relazioni tra attività di innovazione e performance rivela una rinnovata attenzione alla diversità di genere nel top management team aziendale. Diversi studi dimostrano che tale requisito della governance contribuisce all'innovazione (Lee & Chung, 2022; Talke et al., 2010; Xie et al., 2020), alla performance dell'impresa (Talke et al., 2010; Yang et al., 2019) e ad un orientamento strategico multistakeholders (Talke et al., 2010). Tuttavia, studi recenti dimostrano che le imprese con un maggior numero di donne nel board direzionale generano meno innovazioni d'impatto e sono capaci di generare una crescita cumulativa e sistemica nel mondo produttivo (Lee & Chung, 2022), atteso che una prevalenza della componente femminile nel board, si correla ad una minore propensione al rischio rispetto alle imprese con un maggior numero di dirigenti uomini (Yang et al., 2019).

Nonostante l'innovazione ed il genere costituiscano un filone di crescente interesse, mancano ancora studi che mirano a comprendere quali fattori, inclusa la componente di genere, e quali risorse nella PMI rappresentino condizioni necessarie e sufficienti per promuovere un'adeguata performance economico-finanziaria.

Obiettivo del paper. Questo studio mira a investigare la relazione tra gli input di innovazione e le performance reddituali nelle PMI innovative, osservando quali combinazioni di investimenti in R&S, capitale umano qualificato e proprietà intellettuale sono in grado di generare elevata redditività delle vendite. Al fine di comprendere anche la valenza discriminante della variabile di genere, l'analisi esplora tali combinazioni distinguendo le PMI innovative a conduzione femminile dalle altre PMI innovative. Lo studio si pone l'obiettivo di offrire contributi empirici al dibattito accademico sulle determinanti dello sviluppo delle piccole e medie imprese innovative, con particolare riferimento all'imprenditorialità femminile. Inoltre, esplorando l'interazione tra i driver dell'innovazione, lo studio mira a indirizzare verso l'adeguata implementazione delle attività e delle risorse ritenute necessarie e sufficienti al raggiungimento di un determinato outcome.

I risultati forniranno preziose informazioni sulla promozione dell'innovazione nel contesto delle PMI innovative femminili mirando a far avanzare la discussione teorica su (i) gli input di innovazione (investimenti in R&S, capitale umano qualificato, proprietà intellettuale), (ii) l'avanzamento dello sviluppo delle PMI innovative, e (iii) l'imprenditorialità femminile, offrendo anche implicazioni manageriali.

Metodologia. Questo lavoro utilizza il metodo fuzzy-set qualitative comparative analysis (fs-QCA) per investigare il fenomeno in esame. Questa tecnica differisce dai metodi statistici convenzionali (Pappas & Woodside, 2021; Ragin, 2008; Woodside, 2013) poiché esplora come vari fattori causali contribuiscono a un risultato specifico, fondato sull'idea che quest'ultimo dipenda dalla combinazione di caratteristiche causali, piuttosto che sui valori isolati di tali caratteristiche (Ragin, 2008). Questo processo consente di avere un insieme effettivamente conciso di driver, quali fattori di input di innovazione tecnologica che influenzano in modo significativo il risultato finale (outcome).

In accordo con Ragin (2008), sono state calibrate le condizioni o input (investimenti in R&S, capitale umano e proprietà intellettuale) e la variabile di risultato o outcome (performance misurata dal ROS). In secondo luogo, è stata condotta l'analisi delle condizioni necessarie distinguendo il cluster delle PMI femminili dalle altre PMI e, infine, sono state sviluppate la tabella di verità e l'analisi delle condizioni sufficienti seguendo le linee guida proposte da Schneider and Wagemann (2012). Nel presente studio, i termini "presenza" o "assenza" di condizioni sono stati adottati per semplicità come equivalenti di appartenenza e non appartenenza a condizioni o insiemi di risultati (Torres & Augusto, 2020; Zoppelletto & Bullini, 2022) sia per le PMI femminili che per le PMI non femminili. Pertanto, l'analisi delle condizioni necessarie verifica se la presenza o l'assenza di una condizione è necessaria per la presenza (ROS) dell'esito. Per l'analisi delle condizioni sufficienti viene presa in considerazione la soluzione intermedia. Infine sono state effettuate analisi di robustezza modificando le soglie di calibrazione (Skaaning, 2011) e impiegando l'analisi delle condizioni sufficienti e la tabella di verità per l'assenza dei risultati (Zoppelletto & Bullini, 2022).

In particolare, il campione utilizzato si riferisce alle 2.695 PMI innovative italiane con un time-frame di 10 anni (2013-2022) che permette una maggiore comprensione dell'andamento delle performance negli anni. L'imprenditorialità femminile viene evidenziata nel campione considerando la composizione in prevalenza femminile nel capitale sociale e nel consiglio d'amministrazione se superiore al 50% del totale, utilizzando i dati forniti da ciascuna PMI innovativa al momento dell'estrazione (Arcuri et al., 2023).

La scelta del contesto italiano deriva dalla forte caratterizzazione del tessuto produttivo nazionale ancorato al

modello della PMI (Antenozio & Di Berardino, 2023; Matricano, 2023; Vrontis et al., 2020), che nel territorio nazionale trova un solido riconoscimento normativo proprio grazie alla presenza di risorse riconducibili agli investimenti di R&S, proprietà intellettuale e capitale umano qualificato (Matricano, 2023). Inoltre, nel più ampio dibattito sull'imprenditoria innovativa e femminile (Antenozio et al., 2023; Arcuri et al., 2023; D'Angelo, 2012; Vagnani & Proietti, 2023), l'Italia presenta un elevato livello di impegno nello sviluppo dell'innovazione grazie anche alle differenziate politiche di investimento locale che impattano diversamente sulla crescita delle PMI e del capitale umano (Antenozio et al., 2023; Matricano, 2023)

Le variabili presenti all'interno del modello derivano da due diverse fonti: (i) sezione speciale del "Registro delle Imprese" contenente l'elenco di tutte le PMI Innovative operanti in Italia al momento della consultazione secondo la letteratura (Antenozio & Di Berardino, 2023; Arcuri et al., 2023; Cavallo et al., 2020; Matricano, 2023) per il capitale umano qualificato e la proprietà intellettuale; (ii) database AIDA (database del Bureau van Dijk), comunemente impiegato per ricercare, analizzare ed elaborare informazioni economiche, finanziarie e commerciali, tutte le imprese italiane, comprese le PMI innovative (Antenozio & Di Berardino, 2023; Arcuri et al., 2023; Muhammad et al., 2021) per gli investimenti in R&S e ROS.

In particolare, il modello prevede tre variabili di input "Investimenti in R&S", "Capitale umano qualificato", "Proprietà intellettuale". Nello specifico la variabile "Investimenti in R&S" è stata costruita come rapporto tra il totale delle immobilizzazioni immateriali e gli assets totali dell'impresa (Arcuri et al., 2023). Questa variabile è strettamente legata al livello di innovatività di un'impresa (Hervas-Oliver et al., 2021) e ampiamente utilizzata in letteratura (Arcuri et al., 2023; Matricano, 2023). La variabile "Capitale umano qualificato" è misurata attraverso una dummy (0-1) ed è associata positivamente agli utili, redditività ed efficienza operativa dell'impresa (Xu & Li, 2019). La tipologia di interazione tra capitale umano e tecnologia rende le PMI competitive e attraenti, riuscendo a superare le barriere dovute alle risorse limitate e ai fondi scarsi. La "proprietà intellettuale" invece, misurata anch'essa da una dummy (0-1) è riferita all'unicità dell'azienda che porta un vantaggio competitivo, in accordo con la letteratura (Hervas-Oliver et al., 2021; Liu et al., 2023). Infine, l'outcome preso in considerazione è il ROS, indice di performance aziendale espresso in punti percentuali. Questo è indicatore della redditività estraibile dalle vendite ed è sintomo della forza competitiva della proposta di valore emergente dall'innovazione, legalmente tutelata nei mercati di sbocco, nonché rappresenta una proxy delle risorse autogenerate dalle vendite come autofinanziamento (Arcuri et al., 2023) e profitto (Caputo et al., 2022), utili per il futuro sviluppo della PMI.

Risultati. Risultati preliminari evidenziano un'interessante relazione tra le attività di innovazione e la performance reddituale, confutando le premesse teoriche del presente studio. Per gli investimenti in R&S, capitale umano e proprietà intellettuale quali input di innovazione, i due cluster non mostrano differenze specifiche in termini di condizioni necessarie e sufficienti andando a sottolineare come il genere della leadership non sembra influenzare la relazione tra queste condizioni e la performance finanziaria misurata dal ROS. Inoltre, da un lato, nessuna delle attività di innovazione è in grado di spiegare da sola un alto livello di performance e, al contrario, gli investimenti in R&S sono una condizione che da sola non produce efficienza; dall'altro, esistono due percorsi per ciascun cluster che combinano le differenti attività innovative per il raggiungimento di una performance elevata. Il primo percorso accosta gli investimenti in R&S con il capitale umano mentre, nel secondo percorso il capitale umano si combina con la proprietà intellettuale. In questo modo sia le PMI innovative femminili che quelle non femminili possono raggiungere elevate performance finanziarie. Questi risultati sono in linea con la letteratura attuale, confermando l'importanza della concatenazione di attività innovative per il raggiungimento di un risultato ottimale.

Limiti della ricerca. Questo studio presenta alcune limitazioni legate alla natura quantitativa della ricerca. Innanzitutto, lo studio si concentra su un solo paese, una limitazione comune alla maggior parte degli studi quantitativi, che risentono ampiamente dei fattori presenti nei diversi contesti istituzionali, i quali potrebbero limitarne la generalizzabilità delle conclusioni. Tuttavia, l'Italia è considerata un contesto adeguato a indagare la relazione tra PMI e sviluppo innovativo grazie alla considerevole variazione e distribuzione del campione su eterogenei clusters geografici aventi tassi di sviluppo socio-economico differenziati. In secondo luogo, la comprensione attuale degli input di innovazione risulta ancora frammentata, per cui utilizziamo solo tre variabili di innovazione quali dati quantitativi, trascurando l'analisi della dimensione qualitativa di tali risorse, in termini di contenuti del brevetto, tipologia di capitale umano, ambito degli investimenti in R&S, elementi che potrebbero indirizzare futuri sviluppi della ricerca. In terzo luogo, ci sono diversi modi per calibrare le variabili nel modello della fs-QCA analisi che potrebbero portare a risultati diversi. Studi futuri potrebbero esplorare differenti dimensioni della governance, quali le forme di imprenditorialità giovanile e straniera, nonché ulteriori elementi di innovazione generando nuovi risultati e arricchendo la letteratura accademica sull'argomento.

Implicazioni manageriali. Le due principali implicazioni teoriche di questo studio si riferiscono, da un lato, all'evoluzione della misura tradizionale dell'input di innovazione come gli investimenti in R&S, in quanto, oggi, questa variabile è da considerarsi non sufficientemente esplicativa dell'innovazione, soprattutto nelle PMI. Di conseguenza, abbiamo proposto altre variabili utili a valutare tale fenomeno, che potranno essere utilizzate in futuri studi empirici per valutare l'innovazione nelle PMI innovative, contribuendo alla RBT e alla comprensione delle risorse strategiche interne per l'innovazione. D'altro canto, proponiamo di studiare l'innovazione nelle PMI con un approccio metodologico innovativo come la fs-QCA. Inoltre, questo studio mira a offrire anche diverse implicazioni manageriali relative all'innovazione e alla performance delle PMI. In primo luogo, suggerisce che gli investimenti delle PMI in R&S non sono

più sufficienti da soli a migliorare la capacità delle PMI femminili e non femminili di generare un livello importante di performance. In secondo luogo, da un punto di vista strategico, le PMI devono indirizzare le proprie scelte di investimento verso un combinato sviluppo delle attività di R&S, formazione e valorizzazione del capitale umano e tutela della proprietà intellettuale.

Originalità del paper. L'interesse verso la trasformazione tecnologica e l'avanzamento digitale e innovativo del mondo attuale ha spinto molte imprese, di piccole e grandi dimensioni a perseguire queste iniziative. Tuttavia, gran parte della ricerca si è concentrata principalmente sulle grandi imprese e, studi sulla performance delle piccole e medie innovative, trascurano la visione sistemica della interazione tra input diversi dell'innovazione. D'altro canto, studi specifici sulle piccole e medie imprese innovative a conduzione femminile necessitano di maggiori approfondimenti proprio per la dimensione dei driver di innovazione. In questo articolo, proponiamo di colmare queste lacune nella letteratura andando ad indagare la relazione tra le attività innovative perseguite e performance finanziarie, concentrandoci sul ruolo dell'imprenditorialità femminile all'interno delle PMI innovative. Dato il background teorico, lo studio si propone di indagare la presente relazione con una metodologia di crescente attenzione (fs-QCA), che differisce dai modelli statistici convenzionali e che cerca di esplorare come diversi fattori contribuiscano ad un risultato atteso e specifico, fondando la sua struttura sull'idea che uno specifico risultato dipenda dalla combinazione di caratteristiche causali piuttosto che sui singoli valori. In particolare, questo studio è tra i primi che indaga il modo in cui diverse combinazioni di attività innovative portino ad elevate performance finanziarie nelle PMI innovative con una ulteriore focus sull'imprenditorialità femminile.

Beyond Words: Leveraging Language for Strategic Decision-Making in Innovation

FRANCESCA CAPO¹ MARIA RUCSANDRA STAN² FRANCESCA DI PIETRO³

Abstract

This short paper is a work in progress in which we aim at investigating the role of language in how teams make sense of disruptions and cope with uncertainty during strategic or innovative-related decision-making. Lately, scholars have been focused on the influence of temporal structure on how teams restore action after disruptive events and retrospectively make sense of the disruptions (Awati & Nikolova, 2022; Sandström & Schildt, 2022). In this body of literature, we propose an emphasis to understand how language affects the decision-making of teams in uncertain circumstances using the theoretical lenses of sensemaking. To do so, by collaborating with a leading strategic innovation company based in Switzerland, we aim at performing a research experiment at the team level using video ethnography observations and open-ended questionnaires to collect feedback. We believe our work can contribute to literature on strategic innovation and decision-making, as well as providing interesting insights for managers and companies operating in international markets.

Key words: *innovation; decision-making; uncertainty; research experiment.*

Framing of the research. *Language is a multifaceted and complex construct (Brannen et al., 2014) that is essential in “the process of constructing organisational, social, and global realities” (Lauring & Klitmøller, 2015: 47). Scholars have demonstrated how foreign language can have a significant influence on an individual's cognitive abilities (Baddeley, 2003), decision-making (Keysar et al., 2012), and attitudes towards innovation (Hadjichristidis et al., 2017). Language diversity within teams can be acknowledged through several indicators, including the number of languages spoken, the level of proficiency, and the influence of diverse backgrounds on interpretation (Kassis-Henderson, 2005). Moreover, it is important to differentiate between language and communication, as both have distinct implications and play key roles in the diffusion of information. Language skills refer to the ability to use specific sounds and grammatical structures of a particular language to convey meaning (Brannen, 2004), while communicative competence involves the ability to establish deeper and more effective agreements and understanding through discussion (Leung, 2005). Language skills are embedded in individuals (Angouri & Piekkari, 2018), and can influence team dynamics (Welch et al., 2005), whereas communicative competencies depend on both the sender and receiver of the message (Karhunen et al., 2018). The complementarity between language and communication enables individuals and teams to create shared meaning (Cohen & Kassis-Henderson, 2012).*

According to research, using a variety of linguistic resources to create meanings and exchange knowledge about strategic and innovative solutions during the development of new ventures can have significant consequences for decision-making (Snihur et al., 2021). In the context of decision-making, language also serves as an advantage in team power dynamics where linguistic factors (e.g., proficiency disparities) influence the members' ability to use power sources, including hierarchical positions (Tenzer & Pudelko, 2017), which in turn affect collaboration and decision-making. Additionally, studies have shown how individuals engage in continuous sensemaking and feedback integration to navigate the uncertainty surrounding decision-making, particularly when undertaking decisions related to innovative solutions (Pryor et al., 2016). This integration involves ongoing language use and social interaction among team members as they attempt to understand ambiguous situations and new events.

A recent review by Whittle et al. (2023) categorised the sensemaking literature, discussing how the organisational meaning-construction process is linked to the distinct functions of the different linguistic forms, based on three approaches: language and cognition, language and discourse, and language and social practice. The cognitive linguistic approach highlights the role of language in reflecting and shaping the mental structures and in understanding how people interpret circumstances and actions (Hill & Levenhagen, 1995). This area of research defines the frame as a mental

template through which individuals make sense of their environment (Walsh, 1995). The second line of research is the critical discursive perspective that focuses on the structures of meaning through which individuals comprehend and exert power, where discourses incorporate the “systems of thought” (Phillips et al., 2004). The third line of research is that of language and social practices that cover different perspectives, including narratives, rhetorical, and interactionist perspectives. The narrative perspective views language as a storytelling tool that structures discursive forms to support individuals in understanding their experiences (Brown et al., 2015). From this perspective, language is pivotal in shaping a new reality for organisational members (Dunford & Jones, 2000). The rhetorical approach highlights the persuasive nature of language in shaping the “sense-making” of different stakeholders (Maitlis & Lawrence, 2007). This persuasive use of language, also known as “sense-giving” (Gioia and Chittipeddi, 1991), aims to influence other individuals’ interpretation and understanding of information in shaping a desired perception of reality. Strategies of persuasion include lexical choices, content, and tone of language (Bilgili et al., 2017). The interactionist perspective views language as a tool for observing real-time interpretations and actions that shape social organisation within a group (Weick, 1995). This approach highlights various forms of interaction, including strategic decision-making (Rouleau & Balogun, 2011), power dynamics (Tourish & Robson, 2006), cue interpretation using frames (Bolander & Sandberg, 2013), work group coordination and collaboration (Einola & Alvesson, 2019), and technology and material artefacts (Cornelissen & Werner, 2014). Within the interactionist approach numerous methodologies have been employed, including the micro-ethnographic technique of analysing video recordings of healthcare teams (Christianson, 2019), grounded analysis primarily in observational data (video-audio recordings and transcripts) (J. S. Liu & Lu, 2012), and ethnomethodologically informed discourse analysis of tape-recorded meetings (Whittle et al., 2016).

Purpose of the paper. Until the early part of the 21st century, language in the realm of business and management lacked the formal recognition it deserved, unlike the closely associated concepts of culture and communication. While occasional mentions of language might have surfaced in subdisciplines like marketing, communication, and international business (IB), there was no cohesive research community or significant focus on the subject. The publication of special issues in *International Studies of Management and Organization* in 2005 (see Piekkari and Zander, 2005) and the *Journal of World Business* in 2011 (see Piekkari and Tietze, 2011) marked pivotal moments in highlighting the emergence of active researchers in this area. Finally, in 2014, the *Journal of International Business Studies (JIBS)* (see Brannen et al., 2014), renowned as the leading IB journal and the sole publication used by the *Financial Times* for its global journal rankings, released its inaugural special issue dedicated to this topic, further solidifying the significance of language in business and management literature.

This study aims to contribute to the field of innovation by highlighting the influence of language diversity (i.e., variety of languages spoken within a group of people) on team strategic or innovation-related decision-making using the theoretical lenses of sensemaking. Both ‘sensemaking’ and ‘language’ are dominated by the concept of uncertainty, as sensemaking helps actors navigate uncertain situations and make decisions in rapidly changing contexts as innovative ones (Sandström & Schildt, 2022), while language involves a degree of uncertainty and change in how it is used and understood (Degen, 2023). Research defines sensemaking as the process of creating meaning and understanding in complex and uncertain settings, while decision-making involves the selection of a course of action based on this understanding (Brown et al., 2015; Parmar, 2014). On the one hand, sensemaking lays the foundation for decision-making by shaping how individuals perceive and interpret their surroundings (Winch & Maytorena, 2009). On the other hand, decision-making provides feedback and new information that can influence future sense-making (Lipshitz et al., 2006). These interconnected processes mutually influence each other in organisational settings such as teams.

To advance the literature within the realm of management, in particular in entrepreneurship and innovation, we make use of different literatures that have dealt with the role of language diversity in team decision-making, including international business research (Brannen et al., 2014; Hadjichristidis et al., 2017; Tenzer & Pudielko, 2020; Volk et al., 2014) and organisational studies (Brannen, 2004; Kassis-Henderson, 2005; Lockwood et al., 2019; Rouleau & Balogun, 2011; Tourish & Robson, 2006; Whittle et al., 2016, 2023). However, our paper aims to contribute to the role of language diversity in innovative and entrepreneurial decision making, hence, we also integrate with emerging literature from strategy and entrepreneurship (Pryor et al., 2016; Welch et al., 2005), as well as linguistics (Degen, 2023; Leung, 2005), and psychology (Keysar et al., 2012) when appropriate. We employ an experimental method to replicate the decision-making procedure using a software designed to enhance innovation skills in organisational settings (e.g., Sparkademy). The feedback module (i.e., proxy for the decision-making process) within this software also includes the feature to record real-time interactions among team members. With our methodological approach, we respond to the call for contributing to the field of sensemaking by examining the relationship between language and decision-making processes through multimodal analysis (e.g., video-ethnography) (Whittle et al., 2023). This study is grounded in the interactionist perspective, which seeks to examine real-time decision-making processes within a multilingual team. However, we recognise the cognitive linguistic approach as a foundation for understanding how individuals interpret situations and actions, as well as the role of language in conveying meaning and information from team members. Hence, we aim to explore how language diversity is integrated into social interactions, while being mindful of the cognitive processes as antecedents of our results (Baddeley, 2003; Volk et al., 2014).

Methodology. Recent literature in entrepreneurship and innovation have highlighted the need to further empirical research in these fields using research experiments (Stevenson and Josefy, 2019; Williams et al., 2019; Grégoire et al., 2019; Morales et al., 2017). We answer this call by employing a research experiment to understand how language diversity influences a team’s innovation decision-making process. The research experiment at the team level will be supported by using video ethnography observations and open-ended questionnaires to collect feedback. At first, we aim

to conduct a pre-pilot test and non-intrusive observations with PhD-level students (around 16 individuals) to collect preliminary results and improve our experiment. Subsequently, once adjustments have been made, a pilot with master-level students from innovation and entrepreneurship courses. We plan of involving in the pilot around 90 master-level students, who will be divided into groups of three people for a total of 30 groups, where 15 groups speak the same language (i.e. common language is the individual's native tongue) and the other 15 groups were language-mixed (e.g. lingua franca is English). In particular, the control group will be the Italian-speaking group (i.e., native language group), whereas the mixed language groups include both those groups where the lingua franca is no one's mother tongue, as well as groups that will be able to capture the relative majority of language choice. This setting allows us to have at least three iterations of interaction among team members. Students will be recruited from master level course in an Italian university that includes both native and Erasmus students. Hence, participants will speak a different language, as well as they will have different levels of English proficiency (students will be assessed on their proficiency using the LexTALE test⁴). The experiment will be conducted in a virtual space. We modelled our pilot test research design based on previous studies using business students as proxies in business decision-making contexts (Song et al., 2022) to evaluate the launch of a new product (i.e., innovation setting).

To simulate the decision-making process, we collaborate with Sparkademy (a leading strategic innovation company based in Switzerland) which gave us access to part of their three-part module (aimed to tackle corporate innovation), in particular, they offered us the feedback module. We envision feedback as a proxy for the decision-making process of team members. In this module, participants are required to evaluate their team members on their LinkedIn CV. The completion of the module is approximately 1.5 hours. In the introduction, the Sparkademy module instructs the participant on how to provide constructive feedback through an interactive video. Subsequently, team members will have to introduce themselves, including their country of origin, and share stories about the great feedback they have received. Once instructions and introductions have been performed, the module then develops into four exercises: i) preparing for constructive feedback, in which participants exchange their LinkedIn profiles and then proceed to deliver written feedback (individual task); ii) sharing feedback with the team (team task); iii) reflecting on the received feedback (individual task); and iv) asking for further feedback (team task). All these parts are performed on the Sparkademy platform, which has the option of recording the video of team dynamics when exchanging feedback. Subsequently, an individual questionnaire will be used as a follow-up to map the decisions taken following the received feedback.

Expected results. The current study aims to understand which and how language characteristics (i.e., language choice, language structures, or frames) that are critical for teams when engaging into sensemaking and trigger peculiar mechanisms of decision-making in innovative contexts. The preliminary results of non-intrusive observations have shown how the feature of language diversity that defines our sample, influences those groups where their native language is spoken, leading to a smoother team interaction and enhanced intra-team comprehension. In contrast, we expect that in teams where English is the lingua franca, sensemaking may be hindered due to misinterpretations and difficulties of comprehension leading to understandings and decisions that might not be shared and fully comprehended by all team members. In fact, interacting with team members in English and thinking in their native language affects how individuals understand problems, feel emotions, and therefore make decisions (Keysar et al., 2012). The difference lies in how foreign and native language processing varies regarding instinct and conscious thought (Costa et al., 2014), and approach towards innovation (Hadjichristidis et al., 2016). Moreover, as a result of the distinct language structures present in the languages of team members, variations in reactions and final decisions following feedback are anticipated. This is because language structures have an impact on perceptions, thoughts, and actions (Chen, 2013; Hechavarria et al., 2017). This is a work in progress and the final results will be available following the research experiment and online survey.

Research limitations. Our work in progress entails some limitations. First, it focuses on a sample of students, and this choice may limit research's generalisability. Second, decision-making related to strategic innovation usually involves several factors, as a complex set of values and characteristics may play a role in this kind of decisions; however, empirically we were limited in the choice of factors (and variables) we could include in the experiment. Future research may address these limitations by replicating the experiment in other settings and including different variables which may influence the relationship between language and decision-making.

Managerial implications. This research aims to provide entrepreneurs and managers with recommendations to leverage language as a strategic tool in organisational activities to undertake innovative decisions. Indeed, the role played by language-structure in different firm's activities point to potential applications in terms of value creation, competitiveness, creativity, innovative outcomes and the creation of a more inclusive environment. Alongside language-structure, also language choices have key implications for organisations: a multilingual environment within firms may foster diversity in activities related to goal-definition and resource allocation, allowing for a more informed strategic planning, with positive returns for firms and for the economy in general. Indeed, research has shown that multilingualism may spur economic growth (World Economic Forum, 2018 - [ps://www.weforum.org/agenda/2018/02/speaking-more-languages-boost-economic-growth/](https://www.weforum.org/agenda/2018/02/speaking-more-languages-boost-economic-growth/)), in that it tears down not only language boundaries within the firm but also in its communication flows with stakeholders, customers and investors.

Originality of the paper. *Our research aim at contributing to several streams of the scientific literature. First, results will inform strategic and management literature by fine graining the mechanisms through which language impacts on innovative decision-making. Second, our research project will inform entrepreneurship literature, which has started investigating the role of language in shaping investors' perceptions and triggering specific financial measures (e.g., earnings management; precautionary cash holdings). However, we lack a deep understanding of how these perceptions are shaped and how language can be leveraged when undertaking decisions about entrepreneurial and innovative ideas. Finally, we also contribute to refine the use of research experiments in empirical studies within the fields of entrepreneurship and innovation, as well as we respond to the call for contributing to the field of sensemaking by examining the relationship between language and decision-making processes through multimodal analysis (e.g., video-ethnography).*

Combining innovation and business networks for resource mobilization in the meat sector: a case study

ALESSANDRO PAGANO¹ ELISA CARLONI²

Abstract

This study explores how SMEs in the meat sector mobilize resources for innovation, focusing on the intertwining of business and innovation networks. The research adopts a qualitative approach, based on an exploratory case study methodology, and relies on the business network perspective as the theoretical and analytical lens. The innovative setting under investigation is related to the “Suino della Marca” project in the Marche Region, Italy. Preliminary findings reveal a non-linear project trajectory marked by bureaucratic hurdles and strategic shifts. The startup Impronta Verde emerges as a key actor orchestrating business and innovation networks and addressing challenges such as financial constraints and market uncertainty. The study underscores the importance of resource mobilization, including financial and human resources, and the role of governmental support in fostering collaborative initiatives. While limitations include the preliminary nature of findings and reliance on one round of interviews, the research holds the potential to offer insights into resource mobilization through both business and innovation networks, using creative approaches and establishing new connections among key emerging actors, with implications for theory and practice.

Key words: *innovation networks; meat industry; SMEs; ARA framework*

Framing of the research. *The meat sector has undergone significant transformations in recent years due to emerging challenges and changing factors, such as increased consumer demand for sustainable and ethically sourced products, new technologies advancing production and distribution processes, new markets, and stricter safety requirements (Maples et al., 2019; Golini et al., 2017; FAO, 2017). Such an evolving business landscape requires firms active in the industry to adapt and change strategies and organizational configurations to maintain their competitiveness and pursue new paths in their markets. This implies investing resources in innovative activities, adopting new organizational forms and mechanisms and involving other actors in the supply chain.*

While large firms - often with a multinational dimension - have developed over time adequate capabilities to cope with market uncertainty and changes, small and medium-sized enterprises (SMEs) in the meat supply chain, usually located in rural settings, might face additional hurdles, and suffer a negative impact due to such unexpected new evolutions (Peón and Martínez-Filgueira, 2020). Indeed, SMEs suffer from limited resources in terms of skills, funding, and knowledge, which are essential for the pursuit of innovation processes (Mersico et al., 2023; Radas and Bozic, 2012).

The literature has widely demonstrated that SMEs might recur to networking and collaborative agreements with other firms and organizations, increasingly facilitated by collective initiatives and projects, to obtain access to resources and upgrade their innovative profile to remain competitive (Radas and Bozic, 2012; Ortega-Argilés et al., 2009). Despite the benefits of such collaborative efforts, there is a gap in the literature regarding the mechanisms and outcomes of networking and partnership initiatives among SMEs in the meat sector, particularly concerning resource mobilization for innovation.

Purpose of the paper. *The main objective of this study is to gain a better understanding of the main processes concerning resource mobilization by SMEs active in the meat supply chain while pursuing innovative projects. This analysis will emphasize two distinctive and interrelated aspects:*

- i) the co-existence and intertwining of business and innovation networks, where the business networks are described as the result of informal and emerging interactions between organizations, while innovation networks have a deliberate and conscientious nature, and are guided by consensus among members regarding specific objectives to be achieved (Rubach et al., 2017; Mota et al., 2023);*
- ii) the main patterns concerning resource access, development, and combination (Baraldi et al., 2012; Bocconcelli et al., 2020), in the light of SMEs' limited capabilities.*

In order to address these research objectives this ongoing research adopts the Business Network perspective (Håkansson et al., 2009) and notably its main conceptual underpinnings concerning the nature of business and innovation

¹ University of Brescia

² University of Brescia
e-mail: elisa.carloni@unibs.it

networks (Rubach et al., 2017) and the resource development and mobilization processes, as emerging from the actors-resource-activities framework (Håkansson & Snehota, 1995).

Methodology. The study applies a qualitative case study methodology (Yin, 2003; Halinen & Törnroos, 2005). The case study in focus concerns the “Suino della Marca” innovation project, which has been implemented in the Marche Region, shaped by the initiatives of firms, supply chain stakeholders and organizations of producers, with the aim to create a local quality product based on a genetic line from the Marche Region.

Data collection is ongoing and is based on a combination of primary and secondary data sources. As the primary source of data, semi-structured interviews (Kvale & Brinkmann, 2009) have been conducted to account for the perspective of the main actors involved in the project: Baldi Carni, a local firm active in the agri-food sector which has taken the lead of the project, and Impronta Verde, the newly created startup taking care of brand management and committed to carry through the innovation path by providing resources and know-how. Preliminary interviews have been conducted with (1) the CEO of Baldi Carni and co-founder of Impronta Verde; (2) the Project Manager in charge of the “Suino della Marca” project; (3) the Manager of Impronta Verde. Project factsheets, the companies’ websites, the Marche Region official platforms as well as articles from local newspapers, constitute secondary data sources and have been used to track the project’s process and phases, interdependencies, key facts, and main results.

Data analysis follows a systematic combining approach (Dubois & Gadde, 2002), highlighting the interplay between the research object, methodology, and theory. The empirical analysis relies on the business network approach, and it has been guided by the ARA framework (Håkansson & Snehota, 1995). The ARA framework describes the content of business interaction in three interrelated layers: actors’ bonds, resource ties, and activity links. The three layers are highly interconnected as activities are performed by actors, who use resources and what happens in a specific relationship impacts not only the individual organization but also its relationships and the wider network. The framework appears suitable for investigating the role of key actors, both existing and emerging ones, the nature of activities carried out within and beyond the project’s boundaries, and the relevant resource mobilization processes.

Results.

1. Empirical findings

The “Suino della Marca” project started in the early 2000s with the primary aim of developing an autonomous Marche genetic type, a new breed of pig. The project’s trajectory has not followed a linear path over time and has been marked by significant shifts and challenges over time. Initially launched in 2006, the project underwent an experimental phase but was nearly abandoned shortly after due to bureaucratic hurdles. The project gained renewed attention in 2021 and is now back on track, moving towards full-fledged breeding. Overall, two main phases of the project can be highlighted: the first experimental phase from 2006 to 2009 and the second one from 2021 and still ongoing, where a new key actor, Impronta Verde, has taken the lead.

The first phase saw the setting up of the project, sponsored by the Marche Region following the increasing requests of the producer associations (i.e., Consorzio del Salame di Fabriano) and aimed to create a new genetic line - a rustic pig since the region was lacking a native breed - possessing the characteristics of Italian breeds and good zootechnical performance. The main partners of the project were the Marche Region, Università Politecnica delle Marche of Ancona, Università di Camerino, and Assam (now AMAP), which is the Agency for Innovation in Agribusiness and Fisheries “Marche Agricoltura Pesca”.

The universities involved designed and conducted the “hybridisation plan” by developing a crossbreeding program aimed to maximize heterosis and the degree of combinability, using five Cinta Senese boars and twenty Italian Large White sows. The hybridisation plan and crossbreeding program eliminated any risk of inbreeding and provided a high degree of combinability. However, as mentioned above, the hybridization process and the overall project have been stopped due to bureaucratic hurdles, and especially due to the failure of the breeders’ association that was formally the owner of the animals. The project therefore came to a halt in 2009 and remained at a standstill until 2021.

In more recent times, the Marche Region started to search for a firm or organization willing to continue the genetic program already approved by the Ministry of Agricultural Food and Forestry Policies within the national register of hybrid producers of pigs. Emiliano Baldi, owner of the medium-sized company Baldi Carni, expressed interest in taking the lead of the project, aligning with the vision of the company. This led to the creation of the startup Impronta Verde, with ownership of the herd and the involvement of a zootechnical entrepreneur.

However, embarking on such a project entailed major risks for Baldi due to the legacy of the project and of the sow farm and because it implied a substantial change and transition for the company, engaging in a new upstream phase of the supply chain, thus requiring comprehensive management of the pork supply chain. Impronta Verde faced high costs and operational challenges in managing new assets without a market presence, feedback, and economic return and with the need to enlarge the sow farm to reach the economic break-even point.

Impronta Verde has then signed a new agreement with the universities of Ancona and Camerino for the completion of selection and technical assistance in the early stages of breeding and has recently managed to involve two farmers for fattening located in the Marche Region. Marketing and promotion activities, including tests to understand the right sales and distribution strategy to be applied, have been undertaken. To date, B2C channels (Baldi’s shop, butcher’s stores...) are providing a better response, due to the reputation and legitimacy that Baldi has gained in the territory. The long-term objective of the project is to introduce the “Suino della Marca” as raw material in the production processes of other chains and expand genetic efforts by creating a configuration to transfer the breeding while protecting the intellectual property and ownership of the genetics.

Baldi Carni is a founding partner of Impronta Verde and aims to become the orchestrator of a network of breeders to promote a collective actor who is also competitive in accessing public funding, participating in bids, and can acquire critical mass and relevance in the eyes of the public stakeholders. With this objective in mind, Baldi has promoted the creation of a network thanks to the involvement of a consultant active in the setting up of a cooperative organization and the search for breeders in specific territories and marginal areas. The search for new partners is implemented through the involvement of local producers in training sessions concerning key innovative themes in pork farming. This activity is carried out autonomously, in cooperation with the local veterinary services and the Zooprofylactic Institute, generating positive results in terms of interest and public recognition in the local breeders' community. However, at this stage, the active involvement of farmers and breeders in the project is impaired by the uncertainties related to normative and bureaucratic hurdles at the local, regional, and European levels, the diffusion of the African swine plague which requires substantive investments in biosecurity, the changes in prices due to the exacerbated costs of the raw materials following the war and the post-COVID period, and the significant changes in meat consumption.

The “Suino della Marca” innovation project shows synergies with other regional complementary projects, such as “SAImarche”, an itinerant slaughtering project, addressing logistical challenges associated with the lack of slaughterhouses in the Marche Region and of non-full loads. By addressing logistic relationships, it is aimed at small livestock farmers but also agro-tourism farms that want to take advantage of extensive breeding opportunities, but do not know how to transport the animals to slaughterhouses. The project solves the problem linked to the lack of a structured relationship between the various actors (extensive breeders, farms, transporters, slaughtering...) by means of a container to be transported to an area close to a small number of farms for slaughtering purposes. Finally, Impronta Verde is also promoting a project aimed at providing free veterinary services to small farmers to provide them with the requirements to get involved in the “Suino della Marca” project. Summing up, the underlying objective of the “Suino della Marca” project is to provide the region with its own genetic prototype, with a wider horizon to create a stable network of farmers around this new genetic line.

2. Preliminary discussions of findings

Three primary insights emerge for further reflection that can be filtered through the three dimensions of the ARA framework (Håkansson & Snehota, 1995). First, the analysis provides insights into the characteristics of the innovation networks in the meat sector around the new genetic type, especially in terms of the plurality of actors involved, from business to governmental institutions, and universities, and highlighting the emergence of new actors for the purpose of innovation. A key actor in the “Suino della Marca” innovation project is Impronta Verde, an entrepreneurial initiative that formally owns the project, takes care of the brand management, and is committed to bringing the project to an end. This new actor, which interacts with firms (such as Baldi Carni), small farmers, and institutions such as public universities, is also in charge of the creation of a supply chain built around the new genetic line, the coordination of activity between supply chain actors and their aggregation under a common supply chain project. Impronta Verde represents a case of creative entrepreneurship in a complex supply chain context; this actor could play the role of orchestrator, effectively combining and connecting business and innovation networks (Andresen, 2021; Rubach et al., 2017).

The second insight concerns the main patterns of resource mobilization and interaction in place, in terms of access, development, and combination (or lack of integration). When looking at resource development and access in SMEs active in innovation processes, the pivotal role of financial resources emerges: the strengthening of business and innovation networks is a key evolution for gaining access to government support and funding. Also, the importance of organizational resources, in terms of human resources, is highlighted, as shown by Impronta Verde. The role of “orchestrator” is shaped by the availability of adequate personnel as technical complexities emerge and a wider variety of networks and projects have to be coordinated. Finally, synergies among projects and projects' resources are increasingly pursued, in light of the high interdependence among the different phases and actors of the meat supply chain. Such interdependencies and synergies represent an opportunity for fostering collaboration among different actors for the purpose of innovation.

Third, pursuing and implementing resource mobilization and development across business and innovation networks in the meat sector is further constrained by the structural market uncertainty and variability affecting many value chain activities, such as the one related to genotype development, activation of production partners, and marketing and distribution. The development of an innovative project such as “Suino della Marca” could therefore show a nonlinear evolution, shaped by changes of various nature - technological, business, institutional - and by the subsequent “networking” behavior by key actors in business and innovation networks.

Research limitations. *This paper is a work in progress and, therefore, presents various limitations in terms of data collection at this stage. The empirical analysis is based on a first round of interviews with key informants belonging to the leading actors in the business and innovation networks, that is Baldi Carni and Impronta Verde. In the next phases of the research, additional interviews will be planned with informants belonging to other firms and organizations active in both business networks - particularly around the meat value chain - and innovation networks, such as universities and regional governments.*

Managerial implications. *The results of this research have relevant managerial implications. For small- and medium-sized firms and organizations, the pursuit of an innovative project in the meat sector is a very complex challenge for the variety of settings and contexts to be dealt with, increasing the uncertainty concerning both the process and the*

final outcome. Overcoming obstacles and unexpected changes requires i) a careful assessment of the features and combination and business and innovation networks to be involved and/or set up; ii) the ability to effectively mobilize resources through such business and innovation networks, using creative approaches - as shown by the set-up of Impronta Verde - and establishing new connections among key emerging actors.

Originality of the paper. This ongoing study aims to enhance our comprehension of the main processes underlying innovation-related business relationships and networks of SMEs in the meat supply chain, using the “Suino della Marca” project as an explorative case study. The development of this specific area of research seems appropriate in light of the increasing interdependences and newly emerging challenges in the meat sector (Golini et al., 2017; Caccialanza, 2023), such as the abuse and misuse of antibiotics (Van Boeckel et al., 2017; Waluszewski et al., 2021), which require innovative measures (at the product, process, and organizational level) for mitigation and imply the adoption of coordination structures and governance mechanisms within networks.

This paper brings to the forefront the co-existence of business networks and innovation networks, showing different characteristics and only partially overlapping and intertwining with each other (Mota et al., 2023). While the business network appears more consolidated, the innovation networks surrounding the innovative initiative under investigation struggle to emerge and develop. Such difficulties underscore the importance, on the one hand, of fostering SMEs’ propensity to undertake cooperative initiatives promoted by public institutions (Munksgaard & Medlin, 2014) and, on the other hand, highlight the need for the regional government to include well-defined strategies that actively supports the establishment and interaction of business and innovation networks in its policymaking.

The role of purpose in digital companies: a study on Exponential Organizations

FRANCESCO DERCHI¹ NICOLETTA BURATTI² FRANCESCO VITELLARO³

Abstract

The significance of purpose in business cannot be overstated. It acts as a guiding force, steering organisations towards meaningful societal contributions beyond mere profit maximisation. Scholars increasingly highlight its diverse implications for effective management amidst evolving societal expectations and digital transformation. Purpose-driven strategies align organisational goals with broader societal objectives, fostering shared identities among stakeholders. Articulating and centralising purpose within organisational culture and values significantly influences corporate brand identity. In the dynamic digital landscape, purpose emerges as a pivotal element for corporate branding, amplifying credibility, fostering customer engagement, and fortifying organisational resilience. Despite its acknowledged importance, a gap remains in understanding purpose's influence on corporate brand identity, particularly within digital companies. Therefore, this paper aims to address this gap by focusing on the case of Exponential Organizations (ExOs). ExOs leverage digital business models and technologies to grow exponentially while incorporating Massive Transformative Purpose (MTP) as a distinctive characteristic. This study explores how the MTP influences the brand identity dimensions of ExOs through qualitative analysis. The Corporate Brand Identity Matrix (CBIM) model is applied to analyse primary data gathered from in-depth interviews conducted with managers of two selected ExOs, supplemented by secondary data from internal and external sources related to the chosen cases. The paper contributes to the academic discourse on the impact of purpose on corporate brand identity, offering insights into brand differentiation, stakeholder engagement, and strategic alignment in the digital age. Additionally, this research provides managerial implications for brand purpose management, offering valuable insights for managers of digital companies.

Key words: *purpose; digital business model; corporate brand identity; ExO; MTP*

Framing of the research. *The incorporation of qualitative and creative elements within the organisational framework is inherently intertwined with fundamental concepts such as “vision”, “mission”, “values”, “purpose”, and “brand image” (Collins & Porras, 1991; Urde, 2013). This amalgamation is intricately linked to the firm's essence, serving as a strategic asset in management and collectively playing a pivotal role in shaping the organisation's identity (Henderson, 2021). The contemporary academic discourse has again brought this topic to the forefront, echoing sentiments expressed nearly 80 years ago. Indeed, Drucker (1974) characterised the management's neglect of business purpose and mission as a critical factor in business frustration and failure. However, in the present scenario, there remains a persistent challenge in understanding these qualitative elements, often deemed as “fuzzy”, necessitating deeper exploration to grasp their implications for business management. Younger et al. (2020) propose a model that establishes a hierarchical structure, positioning each concept from the core to the periphery of the organisation, progressively encompassing the others. The vision represents the “where” dimension, signifying the organisation's ultimate aim. This overarching level frames the other three dimensions, namely “what” (mission) the firm does/produces, “how” (values) it operates, and “why” (purpose) the organisation exists. The purpose stands at the core of the conceptual framework, emerging as a foundational driver for business growth and reflecting a notable resurgence of interest within the management literature (Henderson, 2021).*

Henderson and Van den Steen (2015) conceptualise purpose as a specific objective for a firm that extends beyond the pursuit of profit maximisation. Mayer (2018) posits that the purpose is rooted in the company's fundamental reason for existence and meaningful contribution to society, shaping its goals and strategic direction (Jimenez et al., 2021). However, the renewed interest in purpose among scholars highlights the intricate diversity of this concept entwined in exploring its implications for business management, particularly in the context of new digital businesses (George et al., 2021; Jimenez et al., 2021).

George et al. (2021) present two perspectives to harmonise definitions of purpose. The “goal-based purpose” focuses on organization-specific aspects, delving into corporate mission, vision, and strategies. Meanwhile, the “duty-based purpose” centres on moral and ethical values, with recent studies exploring company values and organisational engagement in social and environmental initiatives. In this regard, Porter and Kramer (2006) assert that businesses carry a moral imperative, explicitly tying the creation of competitive advantage to their societal responsibilities. This implies crafting a solution beyond corporate philanthropy, emphasising a sustained commitment to generate value for all stakeholders. The overarching goal is to bolster productivity and foster prosperity within the community. Building on this perspective, Aßländer & Curbach (2014) contend that corporations must undergo a transformative evolution, transitioning into a new role as active contributors to the community. This shift involves a departure from a self-centric focus, urging corporations to assume the role of societal actors and exhibit responsible behaviours.

According to Hollensbe et al. (2014), an organisation's purpose involves cultivating a shared identity that aligns shareholder value with broader societal goals. The nexus between corporate and social purposes becomes pivotal, facilitating the alignment of business objectives with heightened political awareness and increased social engagement (Lawton et al., 2020; Patriotta, 2021). Accordingly, Vredenburg et al. (2020) delineate purpose-driven strategy as a deliberate stance on socio-political issues, intending to effect social change and achieve marketing success. Furthermore, Mayer (2021) underscores the imperative for companies to meticulously identify, articulate, and centralise their purpose within their operations. This exertion substantially shapes organisational identity, culture, and values, highlighting the critical significance of delineating how companies present themselves to customers and employees. This strategic process assumes a pivotal role in the creation and effective communication of image and value.

In light of these considerations, the purpose has recently assumed a central role in shaping the corporate brand identity (Urde & Greysen, 2016), primarily due to its ability to make the company's societal impact visible (Annweiler, 2018). Hajdas and Kleczek (2021) advocate purpose-driven branding initiatives, emphasising their potential to empower users, stimulate transformative processes, and contribute to social and cultural impact. This strategic approach is an impetus for developing innovative managerial practices, allowing brands to broaden their societal influence, sway customer perceptions, actively contribute to social change, and enhance their value. The current dynamic landscape of consumer expectations underscores the imperative for brands to provide functional benefits and exhibit a clearly defined social purpose (Henderson, 2021). Therefore, credibility, considered a pivotal factor by stakeholders, can be enhanced through purpose, manifesting the organisation's essence (Cullinan et al., 2021). Calder (2022) also advocates for the seamless integration of a brand into its positioning, affirming its integral status within the larger context. Hence, embracing a defined purpose confers substantial advantages to a brand and is crucial in enhancing community outreach (Hsu, 2017). This perspective resonates with Bonchek's (2013) emphasis on customers actively seeking inclusion, a sense of belonging, and opportunities for meaningful engagement.

The prominence of corporate brand identity and purpose has heightened with the onset of the digital era, especially among born-digital companies (Mingione & Abratt, 2020). Digital technologies offer unparalleled opportunities and challenges in today's business environment. Nevertheless, the field of branding has yet to fully adopt the dynamic mindset essential for navigating this rapidly evolving landscape (Von Wallpach et al., 2017). Emerging brands leverage the digital wave, utilising digital business models to create value with consumers while prominently highlighting their values. Within this context, a brand identity rooted in a solid and credible purpose enhances the customer experience and is a strategic differentiator in the competitive digital landscape (Filho et al., 2024). It also amplifies the effectiveness of digital marketing efforts and employee engagement (Birkinshaw, 2019). Veloutsou and Guzman (2017) underline technology's significant impact on daily consumer lives, highlighting the pivotal role of social media in consumer empowerment. Therefore, a prominent online presence that aligns with the corporate purpose cultivates transactional trust and ensures the brand is recognised and valued across diverse digital platforms (Veloutsou & Guzman, 2017). Additionally, a well-defined brand purpose empowers digital companies to swiftly adapt to rapid changes and emerging trends while maintaining a distinctive core brand identity.

Purpose of the paper. Purpose emerges as a pivotal factor in shaping brand identity, providing stakeholders with heightened clarity regarding their affiliations and the brand's overarching commitment to social and environmental issues (Cullinan et al., 2021). The purpose becomes a pertinent component of brand identity (Mirzaei et al., 2021) and is intricately linked to its inspirational aspects, extending beyond mere profit considerations. Thus, the brand purpose can elicit specific perceptions and profoundly impact consumers (Filho et al., 2024). Notwithstanding advancements in the study of brand purpose, the academic inquiry remains incipient (Narayanan and Das, 2021). Recent exploratory investigations suggest the potential of brand purpose to engender value for consumers and contribute to brand equity (Hsu, 2017; Annweiler, 2018; Hajdas & Kleczek, 2021; Williams et al., 2022; Filho et al., 2024). However, a gap exists in the literature, as extant research has not explicitly delved into the ramifications of purpose on brand identity. Specifically, there is a dearth of studies into how and to what extent purpose influences the various dimensions of brand identity, particularly the implications for value creation stemming from consumers' and companies' perceived value of purpose. Furthermore, although significant expertise has been cultivated in comprehending product/service brands, the same level of understanding is lacking regarding corporate brands and related issues (Urde & Greysen, 2016). The lack of studies focusing on companies adopting a digital business model encompassing both born-digital and transformative digital enterprises appears notable, given the anticipated substantial benefits of integrating purpose into brand identity management.

Hence, this paper seeks to contribute to the nascent academic literature on brand purpose management by addressing the following research question:

RQ: How does the integration of purpose influence the building of corporate brand identity in companies implementing a digital business model?

The paper aims to comprehend the mechanisms and extent to which purpose can influence and yield benefits for corporate brand identity across all dimensions. Specifically, the study explores how declaring and adopting purpose as a core brand value can enhance the value proposition.

Methodology. *Two primary considerations guide the selection of the research methodology. First and foremost, the nature of the research question significantly shapes the choice of methodology, favouring a qualitative research approach as the most suitable means to examine this complex phenomenon thoroughly. Secondly, qualitative methodology is considered a preferred research option for scholars investigating business identity, particularly the “softer aspects of management” that include the purpose (Henderson, 2021). Balmer (2001) also underscores the importance of case study research, recommending naturalism in investigating business identity management. Applying case study methodology is also considered indispensable in the early stages of theory development (Gill & Johnson, 1991). This is notably pertinent in analysing the case surrounding the scrutiny of brand purpose.*

In this qualitative investigation, we focus on Exponential Organizations (ExOs) as they present a substantial case study to address the research question. ExOs represent a contemporary phenomenon with disruptive implications stemming from the digital revolution. Coined by Ismail et al. (2014) in their seminal work, “Exponential Organizations: Why New Organizations Are Ten Times Better, Faster, and Cheaper than Yours”, the ExO concept delineates a distinct category of digital enterprises “whose impact or output is disproportionately large - at least 10 times larger - compared to its peers because of new organisational techniques that leverage accelerating technologies”. Prominent examples of ExOs include Airbnb, Google, and Spotify, exemplifying the success achievable within this unique category of digital firms. Since the book's publication by Ismail et al. (2014), a robust community of practitioners has coalesced, evolving into what is now recognised as the OpenExO Community. This community has burgeoned into a global movement, encompassing more than 6,500 individuals from 130 countries (Allen, 2020). This growth has facilitated Ismail's establishment of a business consultancy grounded in ExO principles, harnessing practitioners as a dynamic community capable of serving as a reservoir of on-demand personnel.

From an academic standpoint, Marchese et al. (2020) undertook a comprehensive literature review to delineate the key elements characterising ExOs. Their work identified three primary strands within the literature contributing to understanding the ExO concept: organisational design, strategy, and technological innovation. According to their findings, an ExO is defined as an entity that can enhance its dynamic capabilities by amalgamating digital technologies, experimentation, and autonomy in organisational models. This adaptability allows the ExO to align with its context and achieve exponential results fully (Marchese et al., 2020). Pompa (2019) supplements this perspective by asserting that the success of an ExO hinges on two critical factors: access to information technologies and innovative organisational models. In this context, digital business models and technologies emerge as fundamental components that provide the framework for ExOs. Notably, digital platforms serve as the catalysts for exponential growth by effectively matching the demands and supplies of the market. Furthermore, digital platforms present opportunities for scalability, capitalising on positive network effects and fostering business prospects through value co-creation with customers. Each facet of their digital business model is pivotal in the accelerated growth that characterises ExOs.

*Furthermore, our emphasis on ExOs stems from their purpose-driven characteristic. Ismail et al. (2014) explicitly incorporated the concept of Massive Transformative Purpose (MTP) as a central element defining an ExO. The MTP serves as the fundamental *raison d'être*, adhering to specific prerequisites, particularly uniqueness. In detail, for an MTP to be deemed Massive, it must possess a global scope and be linked to either a novel or pre-existing abundance (Ismail et al., 2018). The overarching idea is for the MTP to wield substantial influence, harnessing the exponential acceleration of technology. Moreover, the Transformative aspect of the MTP necessitates it to be highly aspirational and inspiring, identifying a dimension beyond current possibilities and contributing to positive global change. This underscores the interconnectedness of these businesses with society, recognising that their prosperity is intricately tied to the well-being of the larger community. Lastly, the Purposeful criterion dictates that the MTP should elucidate the *raison d'être* of the organisation (Ismail et al., 2018), aligning seamlessly with the earlier definition of purpose we discussed previously. In addition to this definition, Dimitrov (2022) has recently contributed to understanding MTP by identifying its core as a cherished culture that engenders significant impact within and beyond the organisational sphere. This culture catalyses effecting profound change, leveraging operational excellence and business innovation as critical mechanisms. Through this lens, the MTP functions not only as a guiding principle but also as a dynamic force that drives continuous improvement and fosters innovation, ultimately leading to tangible outcomes that extend far beyond the confines of the organisation itself.*

In light of the considerations above, ExOs emerge as compelling case studies due to their status as a burgeoning global phenomenon. They encapsulate the two focal aspects investigated in the current study: digital business models and purpose.

We strategically selected two prominent ExOs for in-depth examination: Airbnb, which illustrates the characteristics of a digital-native company, and Mylia, which embodies the outcome of a transformative digital evolution. These organisations operate within distinct sectors, with Airbnb prominent in the hospitality industry and Mylia specialising in learning and development consulting. A compelling and impactful purpose underpins each. Airbnb's MTP of "Belong

Anywhere" resonates globally, addressing the universal human experience and potentially reaching every destination worldwide. This MTP, fostering a sense of being "part of something larger", has been strategically positioned at the core of Airbnb's company culture, representing a significant competitive advantage. Furthermore, Airbnb holds a position in the Unicorn Club, having adopted a digital business model since its inception in 2007, solidifying its status as a digital-native company. This strategic alignment with digital principles has contributed to Airbnb's success and evolution. Conversely, Mylia was established with a fresh perspective and cultural ethos, crafting a new digital business model dedicated to training courses. Today, Mylia is one of the leading entities in the Italian training market. As a part of the Adecco Group, Mylia was launched in 2018 with the MTP of "Advancing Humanity". This MTP was identified during a transformative journey that commenced in 2016. This dual exploration of Airbnb and Mylia provides a comprehensive examination of ExOs operating in different sectors, each driven by a powerful purpose and embodying unique digital business models.

The development of our cases draws upon a combination of primary and secondary data, ensuring a comprehensive and in-depth analysis of the chosen ExOs. This dual-source approach enhances the robustness of our investigation, enabling us to glean valuable insights into the intricate dynamics of digital business models and purpose within the context of ExOs. A rigorous approach was adopted to identify, contact, and actively involve executives from Airbnb and Mylia in systematically investigating the chosen ExOs. Two in-depth interviews were conducted with key managers for Airbnb on April 9th, 2021, and March 17th, 2022. The first manager, a former advertising executive and brand specialist, played a pivotal role in defining Airbnb's corporate purpose, overseeing the Airbnb Community. The second manager holds the position of Country Manager for the Italian market. In the case of Mylia, seven interviews were conducted in April and May 2021. Four of these interviews involved leadership team members, while one manager was the Project Manager responsible for R&D and Innovation. All interviews were conducted remotely using Microsoft Teams as the collaborative platform, ensuring accessibility and efficiency in the data collection process. Simultaneously, primary data from interviews was complemented with information gathered from internal sources, such as corporate reports and documents. Additionally, external sources, including social networks and websites, were explored to augment the dataset. The data was coded systematically using the open-access tool Taguette.

This comprehensive methodology facilitated a meticulous and transparent analysis, adhering to the rigorous standards of academic research in terms of both precision and reproducibility. The interview questions were carefully structured, drawing inspiration from Urde's "guiding identity questions" explicitly tailored for probing the implementation of the Corporate Brand Identity Matrix (CBIM) model (Urde, 2013). We utilised the CBIM Urde (2013) to explore and analyse the collected data from the two case studies. Based on their impact, this matrix categorises dimensions into external, internal, and mixed, establishing interconnected relationships that influence the brand. The harmonious alignment of all nine dimensions and consistent interrelation fortify the brand (Figure 1).

Figure 1. Corporate Brand Identity Matrix (CBIM) model.

Source: Urde (2013)

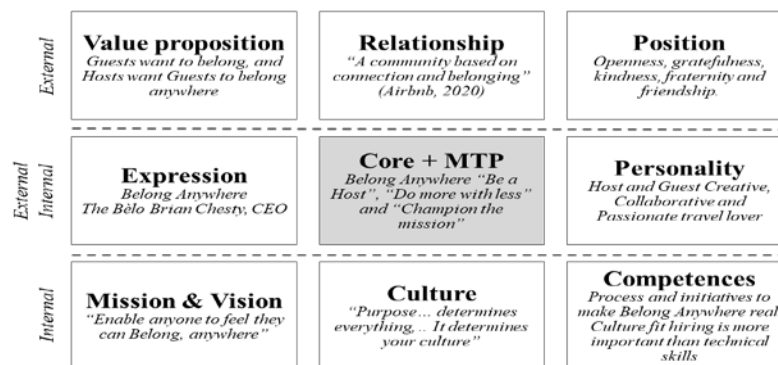

Placed at the centre of CBIM, the "brand core" functions as an analytical tool and an operational guide (Urde, 2013). This dimension defines promises and core values that directly influence the other eight areas of the model. The other dimensions include "expression", which pertains to the verbal and visual manifestation of the brand, and "personality", which focuses on the brand's character. Both aspects simultaneously impact the organisation's internal (sender) and external (receiver) facets. The "mission and vision", "culture", and "competencies" constitute the internal dimension of the brand, closely tied to organisational values. On the other hand, the "value proposition", "relationship", and "position" represent the external dimensions of the brand, concentrating on interactions with both customers and non-customer stakeholders. Hence, the selection of the CBIM model stems from its capacity to offer a dynamic approach to delineating a firm's identity, presenting a comprehensive framework for exploring and comprehending the multifaceted impact of purpose on corporate brand identity. In this context, the MTP (i.e., purpose) is presumed to be integrated into the brand core, playing a pivotal role in shaping and influencing the other dimensions within the CBIM framework.

Results. From the collected information, we identify and describe the corporate brand identities of the two selected ExOs. We present the overall coherence between dimensions and use Urde’s four dynamics (2013) to explain the role of the MTP in creating alignment between them.

The strategy diagonal involves the dimensions of Mission and Vision, Core, and Position. In the case of Airbnb (Figure 2), the MTP “Belong Anywhere” is present in the firm’s mission statement and is often even used when discussing the vision. While also representing the promise of the brand, the MTP is key in clarifying Airbnb’s position in the hearts and minds of customers, being used extensively in advertising and communication.

The horizontal communication requires the dimensions of Personality and Expression to be aligned with the Core. At Airbnb, the MTP has been visually translated into a symbol. The “Bélo” is an abstract figure defined as “a symbol of belonging”. Similarly, Airbnb’s corporate character is represented by its founders, particularly by the CEO, Brian Chesky. He was the first host to rent apartment beds and pioneer Airbnb’s business model. Moreover, he often refers to the MTP when starting his public communication. Amidst the workforce adjustments prompted by the COVID-19 pandemic, he articulated the significant challenge of managing the situation, particularly for a company like theirs, whose mission is deeply invested in fostering a sense of belonging.

Figure 2. CBIM of Airbnb.

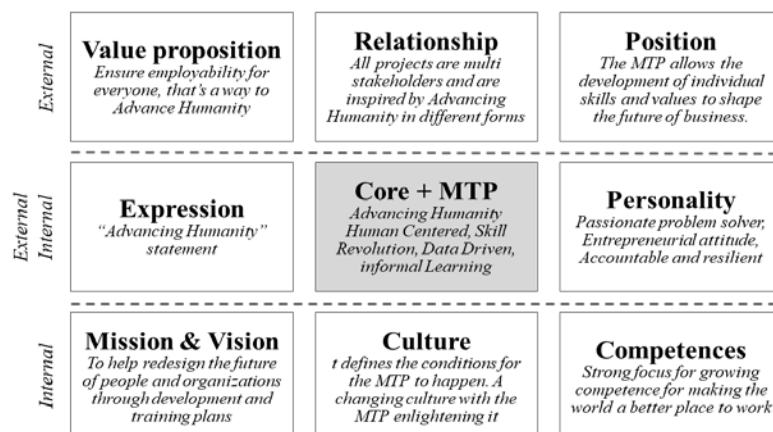

Source: Authors’ elaboration

In the case of Mylia (Figure 3), the MTP “Advancing Humanity” emerges as an element of the Core, inspiring the other eight dimensions of the corporate brand identity.

The competition diagonal involves Competencies, Core and Value Proposition. Since its birth, Mylia has invested in developing internal competencies to improve the world. An example of this can be found in the job description for the role of Learning Designer (Focus on Green Transition). At the same time, the MTP also directly influences the value proposition. “Human Centered” is the first pillar of Mylia’s proprietary L&D framework. As a result, Mylia’s Product Change Academy won the “Prodotto Formativo 2021” Prize as the best learning and development product introduced in the market in 2021 (Polotti, 2021).

Finally, the relationship vertical concerns how the firm deals with various stakeholders. In different interviews, Advancing Humanity emerged as an indirect inspiration for shaping third-party relationships. Team collaboration and a holistic and collective approach to growth are defined as ways to advance humanity. This perspective has played a profound role in the firm’s values. It also emerges in the culture dimension as “a changing culture that involves everyone in the organisation.” The MTP is “a guide for our colleagues... for making this change effective.”

Figure 3. CBIM of Mylia.

Research limitations.

Limitations are specific to each case study and related to the entire research.

First, the study is focused on two organisations only. While exploring this new topic is already useful, it should be considered a step towards a broader and more structured approach. As a second aspect, the two cases have been identified as representative of different industries. However, applying the same approach and extending the reach to two or more firms per industry would give us a valuable, broader perspective and include additional theoretical and managerial contributions. A third point is related to the study's industry coverage. Considering that only two sectors have been approached, it would be interesting to extend the study to a more significant number, for example, according to the digital vortex research (Wade et al., 2021). Fourth, every case study was designed to describe each organisation in a specific period, as identified in previous studies about the brand core (Urde, 2016). It would be interesting to study the ExOs with a longitudinal observation and the management of the MTP over time. A fifth point concerns the number of executives engaged in the research. In the case of Mylia, the number of managers interviewed could be significant, but the Airbnb case featured only two managers. Although they cover a relevant role in the organisation, this can be a limitation, considering the number of stakeholder groups involved in an ExO ecosystem. For this reason, a more inclusive study involving more internal and external perspectives should be undertaken in the future. Sixth, some limitations can be identified in the data types. All primary data have been collected through interviews. Due to restrictions related to COVID-19, some planned sessions for data collection through observations have been cancelled. Taking into account the importance of data diversity when it comes to qualitative research (Bryman, 2016; Yin, 2017), including the ones from observations, it would be valuable to extend the research with more data variety. Finally, a seventh point involves the nature of the work, supported by an inductive method. In the future, it would be interesting to extend the research following a different methodology, such as deductive (Bryman, 2016) or even abductive (Dubois & Gadde, 2002). This methodology, in particular, has already been applied to previous research about corporate brand identity (Urde & Greysen, 2016).

Lastly, when it comes to the definition of further studies, it could be interesting to extend the research to the different ExO attributes as dimensions of the impact of the MTP. The study has revealed that the CBIM cannot fully explain an Exponential Organization's identity. According to the existing literature on Corporate Brand Identity (Balmer, 2001, 2010), exponential attributes like Leveraged Assets or Staff on Demand should be analysed to understand their role as distinctive components of an ExO. It could lead to new considerations about the firm's corporate brand identity and relative dynamics.

Managerial implications. *First, this study contributes to creating systematic knowledge of ExOs, particularly the MTP. ExO scholars have clearly defined this need (Pompa, 2019; Marchese et al., 2020; Dimitrov, 2022). Also, this work is a step forward in validating the MTP concept, addressing the gap between academics and practitioners, as Bansal et al. (2012) described. The MTP emerges as a vital intangible asset within an ExO. Integral to the brand's core, it establishes identity and offers a clear sense of direction, inspiring and challenging the organisation. Simultaneously, the MTP exerts influence across various dimensions: shaping the firm's culture and internal operations, defining the brand and its external engagements, and informing the ExO's competitive strategy.*

Another significant finding from our study corroborates Ismail et al. (2014)'s assertion that the MTP is a fundamental prerequisite for an organisation to qualify as an ExO. According to Ismail et al. (2018), the MTP “defines the core purpose of the organisation's existence”, elucidating the company's aspirations. Therefore, the MTP must possess specific characteristics: it should address abundance, inspire transformation, and articulate the organisational purpose (Ismail et al., 2014). This is evident from our analysis of case studies. Both statements, such as Airbnb's “Belong Anywhere” (Chesky, 2014) and Mylia's “Advancing Humanity”, exhibit characteristics of being both Massive and Transformative.

The findings further indicate that the MTP constitutes a component of an ExO's brand core, as per Urde's model (2016). Our research illustrates that the MTP influences the brand's Promise and Core Values, which define the brand's essence, as outlined by Urde (2013). Therefore, the MTP is pivotal in shaping an ExO's corporate brand identity.

In conclusion, our study, employing the CBIM, has shed light on the significant role of the MTP in the value-creation process of ExOs. It becomes evident that coherence and alignment across various dimensions enable firms to effectively manage their corporate brand identity through the brand core, particularly in navigating diverse business challenges (Urde, 2013). Developing a specific value proposition for an ExO necessitates alignment with the brand promise, the brand core, and, consequently, the MTP. Scholars argue that this alignment is crucial for building reputation and fostering positive customer relationships, ultimately leading to revenue generation. Our research underscores corporate brand identity as a formidable management challenge (Urde, 2013). Furthermore, this aspect is highlighted by applying the competition diagonal, which delineates the managerial dynamic concerning how a firm operates in the market, employing differentiation based on market positioning and the organisation's competencies.

Originality of the paper. *This research aims to elucidate the concept of the MTP, a relatively novel topic in academia (Dimitrov, 2022). Similarly, ExOs, defined as companies implementing a digital business model and technologies, is perceived as a new study area (Pompa, 2021). However, they are relevant to contemporary managerial challenges (Marchese et al., 2020). Consequently, there is a pressing need for dedicated and innovative research efforts in this domain (Pompa, 2019). Moreover, considering Ismail's projection that all businesses will evolve into ExOs within the next decade (Derchi, 2021), the urgency to explore innovative methodologies to study this phenomenon becomes even more apparent (Pompa, 2019).*

In this context, there is a pressing need to develop innovative approaches for studying digital companies, particularly

ExOs, and recognise the practitioner-centric nature of the subject matter. Moreover, delving into the concept of purpose and its ramifications on corporate brand identity unveils potential new pathways for digital company leaders to foster increased mindfulness in their decision-making processes and amplify the effectiveness of their actions.

Data Value Chain and Data Ecosystem through digital and traditional tools

LORIS SANTARELLI¹ FEDERICA CECI² MARIANNA SGAMMOTTA³

Abstract

The adoption of technologies based on data utilization and exploitation have led organizations to embrace new method of gathering information and insights. As data gain value throughout their journey from acquisition to usage, organizations must acknowledge each step of the Data Value Chain (DVC). This model, which forms the core of data ecosystem concept, helps organizations to fully unfold the potential of their data. Despite ecosystems literature have progressively gained importance, there is no common agreement on data ecosystem definition and terminology. Moreover, important core concepts such as relationships, roles, resources, or domain of data ecosystem may lack the required depth. The aim of this paper is to deepen our comprehension of the main characteristics of data ecosystems by focusing on their main component: the data value chain. We selected this unique contest since the national park is an attractive setting where digital and non-digital coexist. Indeed, this is an interesting phenomenon as this context shapes a data value chain fuelled by data coming from both traditional tools and advanced digital tool such as IoTs. By relying on the data value chain framework, this paper analyses how the National Park of Abruzzo, Lazio, and Molise managed the configuration of their data ecosystem. We developed the case study through content analysis of open-ended interviews and documental analysis. By analyzing the ecosystem at the micro level, we unpacked the data value chain examining interactions and technologies involved in each phase. We discuss the importance of both face-to-face and digitally mediated interactions along the data value chain. In addition, we found how technologies are implemented in each phase of the value chain and discussed about implications. We contribute to literature by deepening our understanding of concepts that organizations must configure while managing or participating in an ecosystem.

Key words: data ecosystem, data value chain, innovation, knowledge, communication tools, team.

Framing of the research. *The ongoing spread and development of technologies are opening up new opportunities for organizations to collaborate, share resources, and operate in an increasing interconnected business environment (Dosi, 1982; Kapoor & Teece, 2021). The adoption of technologies based on data as strategic assets drives organizations into transformations, which may involve digitisations of traditional systems, change in management strategies or in decision making processes (Brynjolfsson & McElheran, 2016; Curry, 2016; Curry & Ojo, 2020; O. D. Watch, 2017). Data are increasingly rising in importance since organizations continuously acquire and exploit them from their context (Alaimo & Kallinikos, 2021). However, these advantages are obviously not immediate. In order to extract value from data, organizations must integrate and model them through specific phases that are described by data value chain framework. The data value chain highlights the activities related to data and technologies allowing organizations to catch value from their owned or acquired data (De Simone et al., 2023; O. Watch, 2017). The data value chain is a model that illustrates how the flow of information create value across a series of step: acquisition, analysis, curation, storage, usage (Curry, 2016). It describes the trajectory data taken from the acquisition to the usage (Curry, 2016; O. D. Watch, 2017). Data value chain has its roots in Porter's value chain (1985), a decision support model for those activities that organisations perform to deliver products or services to markets (Porter, 1985). Today, it is considered as a pivotal point of the future knowledge economy thanks to the opportunities it offers for the digital development of economic sectors (DG Connect, 2013). The huge amount of data is not only owned, but also produced, shared, consumed, and reused from various domains. The data value chain has been developed to analyse the activities related to data and technologies within organisational setting and it is placed to the core level of a data ecosystem (Curry, 2016; De Simone et al., 2023). While referring to data, the term ecosystem refers to a set of actors that generate and share data while interacting with each other (De Simone et al., 2023). This consideration of data as a commodity has led to the emergence of a new environment called data ecosystem (Oliveira et al., 2019; Oliveira & Lóscio, 2018). In this context, the term ecosystem relates to a set of actors that generate and share data while interacting with each other (De Simone et al., 2023).*

Since Moore (1993) explored ecosystems in business strategies, the concept gained increasing importance in the academic literature. It is widely accepted that organisations participating the ecosystems can create more value than they

would have by acting alone: they can foster innovation and they can achieve a position of competitive advantage (Adner & Kapoor, 2010, 2016; Cennamo & Santalo, 2018; Jacobides et al., 2018). Organizations become dependent on each other following their mutual benefit provided by the resources they are exchanging (Cavanillas et al., 2016). Curry et al. (2020, p. 20) described data ecosystem as follow: “a sociotechnical system enabling value to be extracted from data value chains supported by interacting organizations and individuals”. According to (Oliveira et al., 2019) the data ecosystem is a complex network formed by interacting actors that collaborate to find, share, or use data to foster innovation, create value, and support new businesses. Consequently, data ecosystems are composed by different relationships in a network of multiple actors that engage data sharing to contribute to a common purpose or value proposition. Thanks to this network, actors extract value from data value chains (Curry et al., 2022) and therefore they can create new value that no single participant can create (Cavanillas et al., 2016). Within data ecosystems, actors can be organizations or individuals taking part and assuming different roles. Key actors include data suppliers and consumers, data and technology providers, marketplace, and end users (Curry et al., 2022).

After its emergence, the ecosystem is supported by continuous interactions among actors who are engaged in data sharing activities. This could lead the ecosystem to a position of advantage within its sector or market (Blijleven et al., 2013). This stage is characterized by significant changes. Academic literature describes these dynamics as adjustments occurring from the inside or influences exerted from outside the ecosystem (Daymond et al., 2023). According to Holgersson et al. (2022) technological innovations and new style of management are two important drivers in ecosystem. Technological innovations ‘enable or are enabled’ ecosystems’ (Holgersson et al., 2022, p. 2). This implies that a new technology can profoundly influence the entire ecosystem. It may cause it to contract, expand, or undergo broader evolution or collapse. According to the authors, new style of management could impact the ecosystem in terms of coordination costs, level of collaborations, and further innovation. These two drivers model the interconnections and the design of the ecosystem (Holgersson et al., 2022b; Kapoor, 2018). As a consequence, interconnections between actors is ensured by the configuration of technologies and the role assumed by actors. As they can assume various roles with different functions, the ecosystem may be orchestrated by a keystone actor (who define and shape the trajectory of the ecosystem) or it could present a distributed configuration between members (Gawer, 2022; Kapoor & Klueter, 2021).

Based on interconnections and the roles of participants, these actors can develop a wide variety of different relationships and levels (Cavanillas et al., 2016; Curry, 2016). Accordingly, ecosystem literature considers three level of ecosystem: core value chain, extended value chain, and big data ecosystem (Cavanillas et al., 2016; Curry, 2016; Curry & Ojo, 2020). The core value chain represents the central element of a data ecosystem. It categorizes the value-adding activities of organizations, allowing them to extract value from their data. The core value chain models the interconnection between direct data suppliers and the data value distribution channels. (De Simone et al., 2023). The second level of the framework is the extended value chain. At this level actors have the potential to influence market dynamics. They are data and technology providers, data marketplace, and data end users (De Simone et al., 2023). Finally, the macro level of the framework is formed by the big data ecosystem. It is a data environment ‘supported by a community of interacting organisations and individuals’ (Curry, 2016, p. 5). According to the author, the big data ecosystems can surround organisations, technology platforms, or entire sectors.

Purpose of the paper. Despite ecosystems literature have progressively gained importance since Moore’s work (1993), our understanding of data ecosystem concept can be deepened (Oliveira et al., 2019). For example, there is no common agreement on data ecosystem terminology. Oliveira et al. (2019) highlighted the non-existence of a commonly accepted definition. In addition, several works often omit or only address the surface of important core concepts such as relationships, roles, resources, or domain of data ecosystems (Åkerman et al., 2018; Gelhaar et al., 2021; Oliveira et al., 2019). In his review, Heinz (Heinz et al., 2022) found a high degree of fragmentation and suggested the need for improving structural clarity of future research. Following, our research question: how do organizations configure the data value chain in a context where digital and non-digital coexist?

Thereby, the aim of this paper is to define and deepen our comprehension of the main characteristics of a data ecosystem by focusing on the core component of the ecosystem: the data value chain. By delving into the data value chain, at the micro level of the ecosystem (Curry, 2016), we have taken into analysis a singular data ecosystem characterized by actors interconnected by different interactions and with (or without) various types of technologies. By unpacking the data value chain, our purpose is to identify the most frequent interactions and the most used tools in each step of the value chain (data acquisition, data analysis, data curation, data storage, and data usage). This examination allows us to understand how actors within ecosystems behave in a complex context, how they interact and collaborate where digital and non-digital elements coexist.

Methodology. To address our aim, we studied a complex data ecosystem comprised of different kinds of interactions: face-to-face and digitally mediated, involving various tools, both technological and traditional. We conducted a qualitative investigation of data and information sharing mechanisms within the National Park of Abruzzo, Lazio and Molise. The Park manages the complex wildlife of central Italy through dedicated efforts and numerous activities, continuously supported by modernization initiatives. Today PNALM is sustained by network of strong personal relationships and communication, fuelled by continuous face-to-face interactions. Additionally, a well-established use of communication tools and ICT regularly supports their activities, such as data collection, data sharing, storage, analysis, and, more generally, information exchange of various typologies. In other words, their network is composed by a huge flow of information sharing within the organisation, occurring through different tools. To ensure the safeguarding of the natural environment and wildlife numerous organizational areas are engaged in activities. These activities include surveillance, data collection as well as other tasks such as geolocalisation, genetic material collection, drafting of

sightings cards. They are all supported by the use of technologies such as radio collars, app, database, and other ITC.

The national park is an attractive setting in which members perform their activities in a context where digital and non-digital coexist. This is interesting since our context shapes the data value chain fuelled by data coming from both traditional tools and advanced digital tool such as IoTs. Moreover, the park is involved in a continuous modernization of its processes and initiatives, adopting and testing new technologies. This innovation process makes it visible our phenomenon of interest. It could be directly observed as it provides high visibility of the types of interactions and the technologies supporting the data ecosystem.

We conducted a documental analysis about information such as the organization's initiatives and collaboration, the involved actors, their activities, adopted technologies, the organizational structure, their future projects, and events. After conducting the analysis, we collected primary data with 16 open-ended interviews. The questionnaire was focused on monitoring activities, technologies, personal relationships, data sharing, external collaborations, and final questions. We interviewed multiple actors within PNALM belonging to different organization's sectors: direction, scientific sector, communication sector, rangers, and a tech company providing IoT technologies. The first interview lasted 2 hours and the subsequent approximately 1 hour. All the interviews conducted have been recorded, transcribed, and coded in order to identify all the relevant topics and develop the case study. Thereafter, we analysed the interviews with content analysis method. It involved three phases: the pre-coding phase has been carried out starting from the development of a dictionary structured with the most relevant concept found. This was a preliminary analysis where we highlighted the most frequent keywords from the interviews looking for relations with the literature (Creswell, 2014). In the coding phase, we deeply analysed the interviews, selected parts of the text, and assigned them to nodes. The selected nodes have been split into sub-nodes based on the contents. 10 variables were identified following the organizational literature and coded into nodes using NVivo software. We based our methodological approach following (Gioia et al., 2013). In order to assign the type of interactions and tools to the correct phase of the value chain, we assigned the identified nodes to the corresponding phase of the value chain. For example, PNALM's activities, such as wildlife geolocalisation, genetic material collection, and drafting sightings cards, are clearly associated with the first phase of the value chain: data acquisition. We applied the same logic for the other phases.

Results. Firstly, this paper analyzed the types of interactions that support the interconnections along all the steps of the data value chain. We found that each step is characterized by a different occurrence of face-to-face and digitally based interactions. Major occurrences of face-to-face interactions were observed during data acquisition and data usage. This means that actors tend to work and collaborate together live, mostly sharing data or information face-to-face in this phase. In contrast, data analysis and curation bring a slight improvement in the use of digital technologies. Subsequently, in data storage phase there has been a good balance between the two types of actor interactions. Indeed, we found that data travel more through ICTs in order to be stored in the database. The exception is mainly represented by the ongoing use of paper sheets. In the data usage phase, we observed a predominance of face-to-face interactions within the organization. The main reasons why traditional means are still used may include: lack of enabling technologies in some areas (for example, where internet connectivity is unavailable or has a limited signal). Additionally, critical issues encountered in the development of a dedicated platform contributed to this reliance on traditional methods.

Secondly, we focused on the typology of the tools used for each phase of the value chain. We found a different use of digital and traditional tools for each step of the value chain. While digital tools such as IoTs or GPS-based technologies are used for data collection activities, the other phases are characterized by a major use of database and analysis software. Turning to traditional tools, we found paper sheets to be the most commonly used tool in our research context. Finally, we identified the types of activities performed by the actors of each step of the value chain. These findings are part of the attempts to construct a link between knowledge management and data value chain.

Research limitations. As this paper is based on a single case study, it may limit the boundary of findings generalizations. This methodology could be replicated to guarantee improved results by multiplying the patterns found, ensuring the enhancement of robustness of the findings (Yin, 2003). In addition, we focused our study on a unique context where digital and non-digital coexist. Thus, further research may be replicated in other contexts with different configurations of ecosystem components or resources. There may be contexts where other technologies have been adopted or where different styles of management are employed. Moreover, in our setting, the core of the ecosystem is completely internal to our organization. Other research may expand our model by selecting an interorganizational's value chain. For example, a decentralized configuration might be studied thanks to external collaboration.

Managerial implications. Thanks to our research, organizations could know how to improve and manage the ecosystem they are involved in. By knowing how they are structured, organizations can exploit the potential advantages of adopting the right configuration of interactions and tools. In addition, they can perform their activities in a manner that ensures data to be managed throughout the entire data value chain. Organizations can anticipate and avoid criticalities such as lack of enabling technologies, communication, and information losses.

This study highlights the significance of both face-to-face and digitally based interactions along all phases of the value chain. Organizations can facilitate the data sharing process and the exploitation of the value that could emerge from it. They must implement the right strategies and configurations in order to ensure a continuous flow of interactions within the ecosystem.

Regarding to technologies, since each phase is characterized by the use of specific tools, organizations can adapt their technological configuration following the value chain. They can foster the adoption of the right technologies for the

right phase of the value chain. For example, we found major problems in data collection step. Organizations may solve the problems emerging in the development of their platform by enhancing collaborations with the app developer. Finally, organizations may consider the development of a centralized database along the value chain to avoid information losses and to allow all the members to have access to data at the right moment they need them.

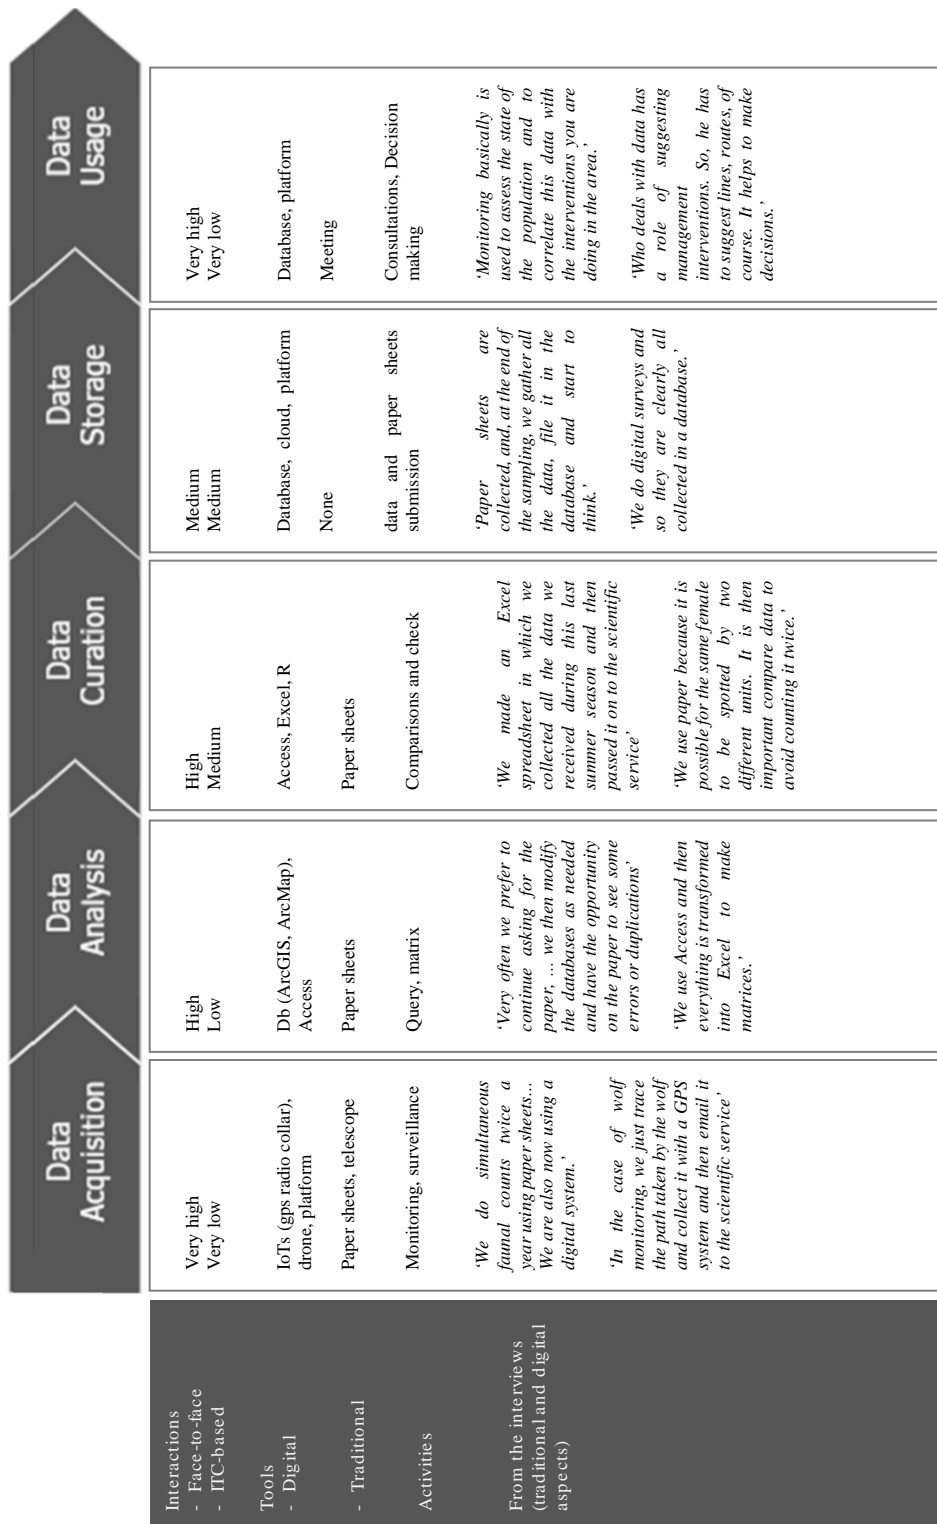

Figure 1 - Data Value Chain from Curry, (Curry, 2016)
 Scale: very low, low, medium, high, very high

Originality of the paper. Data value chain and data ecosystem are two fairly novel topics that are still under explored in academic literature. Our investigation highlights the types of interactions and the technology adopted along the value chain modeled in our context. This study found several challenges and criticalities in the configuration of an ecosystem characterized by both digital and traditional tools. By acknowledge our findings, organizations could take advantages while modeling their value chain, in terms of technology adoption, human resources organizations, and decision-making processes.

Web 3.0: il punto di vista dei manager sulle opportunità e le sfide del Metaverso e degli NFT

CHIARA BARTOLI¹ FRANCESCO FASANO² FRANCESCO CAPPA³ PAOLO BOCCARDELLI⁴

Abstract

Lo studio esamina il punto di vista dei manager rispetto alle opportunità e alle sfide derivanti dall'adozione delle tecnologie del Web 3.0, con particolare riguardo al metaverso e agli NFT. Lo studio adotta un approccio mixed and method su un panel di 100 manager PMI e grandi imprese operanti in Italia e rappresentative di oltre 20 settori, sia nell'industria che nei servizi. Dal lavoro emerge che i manager considerano il metaverso e gli NFT come tecnologie che trovano numerose applicazioni di business e che sono da esplorare in quanto capaci di essere una risorsa distintiva per le imprese e una fonte di innovazione per la generazione di nuovo valore intangibile di mercato. Lo studio evidenzia inoltre le principali sfide che sono legate all'adozione di tali tecnologie e che attengono al know-how, alle risorse e alla sicurezza.

Keyword: web 3.0, metaverse, NFT, innovation, strategy, manager behavior, CEO.

Introduzione e obiettivi della ricerca. *Il Web 3.0 rappresenta un ambiente caratterizzato dalla integrazione di tecnologie basate sui Distributed Ledger, come blockchain, che consentono comunicazioni dirette e sicure tra utenti, l'archiviazione decentralizzata dei dati e la creazione di reti peer-to-peer (Garnett, 2024).*

Il Web 3.0 possiede la capacità di amplificare l'esperienza degli utenti perché consente di vivere mondi virtuali aumentati, di creare alti livelli di coinvolgimento e di immersività, e di scambiare oggetti digitali attraverso i sistemi blockchain. L'adozione delle tecnologie del Web 3.0 ha subito un'accelerazione durante il periodo della pandemia da COVID-19 che si deve alla accresciuta integrazione delle tecnologie digitali negli spazi di vita e di consumo delle persone (Sheth, 2020).

Le caratteristiche delle tecnologie del Web 3.0 anticipano come queste potranno generare profondi cambiamenti nelle modalità di gestione dei processi di innovazione da parte delle imprese (Acciarini et al., 2023; Lumineau et al., 2021; Tapscott and Tapscott, 2017). Tra queste, emerge la rilevanza del metaverso come sistema esperienziale di continuità tra il mondo reale e quello virtuale (Floridi, 2022; Hennig-Thurau et al., 2022). Si stima che nel 2024 saranno venduti oltre 14,3 milioni di dispositivi per la realtà virtuale al livello globale e che il fatturato globale del mercato del metaverso raggiungerà i 678,80 miliardi di dollari nel 2030, fino a sostituire gli attuali social media (Statista, 2023).

Nell'ambito del Web 3.0, rilevanti sono anche i Non Fungible Tokens (NFT), i quali si stanno affermando come game changer in numerosi settori. Infatti, a fine 2022 risultano essere stati scambiati oltre 9 milioni di NFT a livello mondiale, per un valore di quasi 2 miliardi di dollari (Cryptonomist, 2023).

Sebbene si stia assistendo ad una crescita della rilevanza di business delle tecnologie del Web 3.0, e che si deve alla loro capacità di incidere sui sistemi di generazione del valore delle imprese e di agire come motori di sull'evoluzione futura delle industrie (Kraus et al., 2022), tuttavia gli studi sul tecnologie del Web 3.0, ed in particolare su NFT e metaverso, sono ancora limitati ed hanno una prevalente natura teorica. E' riconoscendo questo gap che il presente studio mira ad approfondire la comprensione circa gli impatti di business del metaverso e degli NFT, cogliendo il punto di osservazione dei manager che hanno adottato o che adotteranno in futuro questa tecnologia.

Lo studio intende non solo aggiungere nuova conoscenza teorica circa il fenomeno del Web 3.0 e sui suoi impatti di business, ma anche fornire una visione d'insieme circa le principali opportunità e sfide che sono legate all'adozione di tali tecnologie, al fine di guidare le aziende che ancora non le hanno adottate verso la loro integrazione nei propri modelli organizzativi.

Background teorico

La rilevanza manageriale del metaverso

Il metaverso rappresenta una rete di mondi virtuali 3D e immersivi in cui le persone interagiscono come avatar tra loro e con l'ambiente, come nel reale ma senza alcuna limitazione fisica (Giang Barrera and Shah, 2023). Il termine metaverso è stato utilizzato per la prima volta nel romanzo Show Crash di Neal Stephenson per descrivere il mondo virtuale dell'era del post internet (Lee et al., 2022).

Il termine ha tuttavia acquisito accresciuta rilevanza in corrispondenza con l'annuncio nel 2021 da parte di Facebook del coinvolgimento in questa tecnologia, con la sua trasformazione in Meta (Kraus et al., 2022; Polyviou and Pappas, 2022). Il metaverso non è un'idea nuova, trova infatti i suoi fondamenti nei mondi virtuali del Web 2.0 che negli 2000 hanno consentito agli utenti di sperimentare mondi virtuali (es. Second Life) ed interagire con i loro avatar (Dwivedi et al., 2022; Park and Kim, 2022).

Tuttavia, il metaverso presenta delle caratteristiche peculiari che lo distinguono dalle esperienze precedenti e che sono l'essere un business scalabile (Dwivedi et al., 2022), avere una infrastruttura fisica basata su tecnologia blockchain che abilita la possibilità di produrre e scambiare prodotti digitali, essere caratterizzato dalla possibilità di integrare numerose tecnologie digitali 4.0, come la realtà virtuale (VR), la realtà aumentata (AR), la realtà mista (MR), il 3D e le tecnologie di computer vision unitamente ai sistemi di connettività avanzati (Ali et al., 2023; Giang Barrera and Shah, 2023). Questo consente di arricchire l'ambiente digitale di contenuti coinvolgenti, e raggiungere elevati livelli di immersione (Park and Kim, 2022) di presenza fisica nel virtuale e di interazione sociale (Dionisio et al., 2013; Giang Barrera and Shah, 2023; Hennig-Thurau et al., 2022)

Questi aspetti di rottura rispetto alle tecnologie solo virtuali consentono di vedere il metaverso come una applicazione tecnologica in grado di rivoluzionare le modalità di relazione di mercato in diversi settori (Dwivedi et al., 2022; Hollensen et al., 2022; Park and Kim, 2022) come l'intrattenimento (es. le piattaforme Roblox, Sandbox e Decentraland), il retail e la moda dove il metaverso trova numerose applicazioni come vetrina e spazio di consumo e promozionale per accrescere l'esperienza dei consumatori con i brand (Joy et al., 2022), oltre all'education (Lee et al., 2022) e al turismo (Gursoy et al., 2022).

La rilevanza manageriale degli NFT

Gli NFT (Non Fungible Token) vengono definiti come beni digitali che sono stati autenticati utilizzando la tecnologia blockchain (Zelazsko, 2024). Gli NFT permettono quindi di generare "gemelli digitali" di prodotti fisici con un corredo di informazioni identificative delle transazioni che sono avvenute sin dalla loro creazione su tecnologia blockchain (Colicev, 2022). Ciò consente di aggiungere distintività ai prodotti fisici (Hofstetter et al., 2022) rafforzandone il valore simbolico (Colicev, 2022), ma anche di creare asset interamente digitali che si aggiungono al portafoglio di prodotti fisici delle imprese (Hakkarainen and Colicev, 2023). Si tratta di una possibilità di innovazione che le imprese, soprattutto nel segmento del lusso, stanno già esplorando (ad esempio le collezioni Bulgari o Gucci).

Nel settore del collezionismo, gli NFT hanno conosciuto una decisa espansione a livello mondiale a partire dal 2021 (Nadini et al., 2021) e trovano oggi numerose applicazioni anche nelle industrie creative e dello sport (Wilson et al., 2022), nel settore degli eventi e del turismo (Zhang, 2022). Nel settore del fashion, le imprese hanno iniziato ad integrare gli NFT negli ambienti del metaverso (Joy et al., 2022) accrescendo il valore dei brand attraverso la creazione di community e la partecipazione a eventi esclusivi (Zhang, 2022). Gli NFT trovano anche applicazione nei servizi medici e della finanza (Ali et al., 2023), ma anche nei sistemi di tracciamento dei prodotti lungo tutta la value chain e come strumento di rafforzamento della proprietà intellettuale (Treiblmaier and Sillaber, 2021).

Dai contributi di letteratura manageriale emerge come gli NFT rappresentino degli abilitatori di valore di mercato, aprendo le imprese a nuove modalità di creazione e vendita dei prodotti (Zhang, 2022) modificando l'infrastruttura che presiede alle transazioni e alla determinazione dei prezzi (Dowling, 2022) creando nuove relazioni con gli stakeholder e di mercato (Nadini et al., 2021; Wilson et al., 2022).

Inoltre, facendo leva sui sistemi di decentralizzazione abilitati da blockchain, gli NFT mostrano anche la capacità di trasformare i modelli di mercato tradizionali a vantaggio di nuovi formule disintermediate, o reintermediate da attori digitali (Hofstetter et al., 2022).

Nonostante le potenzialità della tecnologia di riconfigurare i mercati esistenti e di crearne di nuovi (Wilson et al., 2022), tuttavia gli NFT rappresentano ancora una tecnologia in fase nascente, e numerose sono le incertezze legate alla loro adozione, tra cui il livello di sviluppo della tecnologia e la sua interoperabilità, oltre a fattori legati alla sua sicurezza (Giang Barrera and Shah, 2023)

Dall'analisi della letteratura manageriale, emerge che gli studi su NFT e metaverso sono ancora limitati e mancano soprattutto contributi che approfondiscano il punto di vista dei manager rispetto all'adozione delle due tecnologie.

Il Disegno di ricerca. *In coerenza con gli obiettivi del lavoro, volto ad approfondire il punto di vista manageriale sul metaverso e sugli NFT, è stato scelto un approccio mixed and method quali-quantitativo all'indagine, mediante la somministrazione di una survey a domande chiuse ed aperte che ha coinvolto un panel di 103 manager rappresentativi di oltre 20 diversi settori, e appartenenti a PMI e grandi imprese.*

La survey è stata svolta in Italia e ha coinvolto sia manager che hanno adottato, sia coloro che non hanno ancora adottato le tecnologie oggetto di indagine.

Nelle domande aperte è stato richiesto ai partecipanti di condividere i vantaggi e le sfide legate rispettivamente al metaverso e agli NFT. Le risposte aperte sono state analizzate attraverso modelli di analisi testuale software assistiti

mediante il programma T-LAB Plus (versione 10.1.2). Sono state effettuate analisi di parole chiave, di co-occorrenza e di associazione di parole, considerando come parole centrali gli “NFT” e il “metaverso”. I risultati sono stati rappresentati in forma di ego-network, dove la grandezza del cerchio mostra il maggiore numero occorrenze di lemmi di parole nel testo, mentre la dimensione del collegamento indica la maggiore vicinanza tra la parola chiave centrale e quella posta nel raggio del radiale. Attraverso le domande chiuse del questionario sono state analizzate le principali ragioni per cui le aziende dovrebbero investire nel metaverso e negli NFT. Le risposte quantitative sono state elaborate statisticamente utilizzando Stata (versione 17) e sono state rappresentate sotto forma di statistiche descrittive.

Analisi dei risultati

Risultati qualitativi

Una prima analisi dei risultati qualitativi sulle parole chiave all'interno del corpus, permette di evidenziare che queste sono, oltre a “Metaverse” (N=44) e “NFT” (N=24), anche “Mass adoption” (N=16), “Obstacle” (N=12) e “Business Model” (N=10).

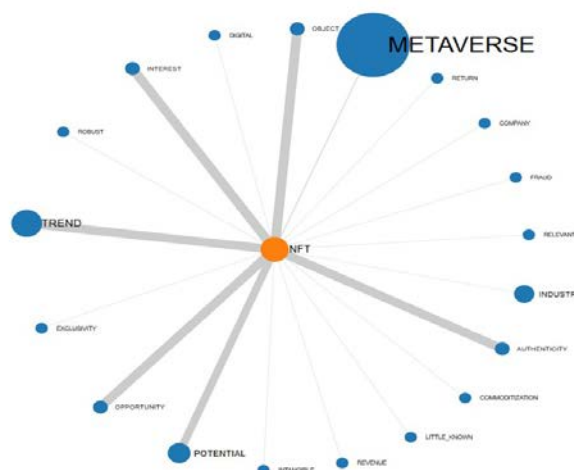

L'ego-network relativo alla parola chiave “metaverso” mostra che il termine è associato con maggiore forza ai termini “mass adoption”, “obstacle”, “technology”, “security” e “investment”. Questi risultati sottolineano la rilevanza degli aspetti che sono ritenuti più critici per i manager

Figura 1. Ego-network per termine “metaverse”

Dall'analisi delle co-occorrenze relative agli “NFT” nel corpus si evince che il termine “NFT” è stato associato più spesso ai termini “trend”, “interest”, “opportunity”, “potential” e “object”. Questo rileva che per il metaverso il panel rileva non soltanto termini che attengono alle criticità della tecnologia ma anche aspetti che ne mettono in risalto i vantaggi di mercato.

Figura 2. Ego-network per termine “NFT”

Inoltre i risultati dell'analisi delle risposte relative alle sfide del metaverso fa emergere la priorità assegnata al lemma "conoscenza", seguita dal lemma "sicurezza". La figura 3 mostra la nuvola di parole relative alle sfide del metaverso.

Figura 3. Word cloud relativo alle risposte sulle sfide del Metaverso e NF

Risultati quantitativi

Per quanto attiene ai primi risultati quantitativi, riguardo al metaverso, circa un terzo dei rispondenti ha già sperimentato il metaverso, e un quarto ha intenzione di farlo in futuro, mentre meno della metà non lo ha ancora sperimentato. Inoltre, emerge un maggiore interesse verso l'adozione della tecnologia del metaverso in alcune aree chiave, quali il marketing, la R&S, e i processi di produzione.

I risultati dell'indagine mostrano anche oltre i due quarti dei manager che hanno pianificato lo sviluppo di nuove soluzioni nel metaverso ritengono di voler investire nell'accrescimento delle skills dei dipendenti rispetto a questa tecnologia, individuando anche le competenze interne che saranno necessarie alle imprese per avviare progetti nel metaverso.

Riguardo alla propensione all'investimento dei manager, il 42% degli intervistati ha dichiarato che investirà sicuramente o probabilmente in soluzioni per il metaverso, mentre il 43% è indeciso e solo il 15% non intende investire. Oltre il 40% degli intervistati ritiene inoltre che il tasso di crescita medio del mercato del metaverso, in termini di ricavi previsti nei prossimi 10 anni, sarà superiore al 40%. Tuttavia, l'80% dei manager/CEO non prevede di investire più del 5% del proprio budget disponibile in progetti di metaverso nel medio termine.

Tra coloro che intendono investire nel metaverso, le principali aree di applicazione in cui si concentrerebbero sono: a) creazione di esperienze immersive per i propri clienti; b) attività di formazione; c) campagne o iniziative di marketing; e d) riunioni aziendali virtuali.

Inoltre, i settori che, secondo gli intervistati, saranno maggiormente interessati dal fenomeno del metaverso sono a) l'istruzione e formazione, b) l'intrattenimento, c) i media e notizie, d) il commercio al dettaglio, e) la produzione avanzata.

Sotto il profilo delle criticità, i manager si soffermano sull'incertezza del ROI degli investimenti di metaverso e quindi sulle reali potenzialità di mercato del metaverso. Un altro aspetto rilevante è la mancanza di competenze specifiche e i problemi di sicurezza relativi alla gestione dei dati (fig. 4).

Figura 4. competenze che i manager ritengono necessarie per la realizzazione di una strategia relativa al metaverso.

Per quanto riguarda gli NFT, il 46% degli intervistati ritiene rappresentino un trend da esplorare. Inoltre, le principali aree che i manager vedono di maggior sviluppo per gli NFT sono la tutela intellettuale, il collezionismo, e il marketing.

Secondo i manager del panel, sebbene si tratti di un mercato di nicchia, gli NFT rappresentano una significativa opportunità di crescita dei ricavi e hanno già dimostrato di avere un potenziale di sviluppo in diversi settori. Inoltre il loro valore potrebbe aumentare in seguito ad una loro adozione mainstream. Tuttavia, circa i 2/5 degli intervistati non considerano i NFT una tecnologia esplorare e su cui investire, poichè il mercato è ancora troppo volatile e quindi il loro valore di business si mostra ancora limitato.

Per quanto riguarda gli aspetti normativi, solo il 17% degli intervistati ritiene che i governi stiano agendo in modo adeguato rispetto alla regolamentazione del metaverso, mentre il 63% ritiene che gli attuali livelli di regolamentazione non siano sufficienti. Secondo questi manager le aree che dovrebbero essere regolamentate nel campo del metaverso riguardano principalmente la sicurezza informatica, l'istruzione e la formazione, le transazioni economiche e la relativa tassazione, nonché il comportamento sociale ed etico per prevenire implicazioni psicosociali potenzialmente dannose.

Discussioni e conclusioni. *I risultati delle indagini qualitative e quantitative dello studio forniscono informazioni rilevanti rispetto al punto di vista dei manager sul metaverso e sulle NFT.*

Per quanto riguarda in particolare gli NFT, il bisogno di autenticità è visto come un driver chiave per l'adozione degli NFT. Questo suggerisce che gli NFT potrebbero innovare significativamente i modelli di business. Infatti, questa tecnologia può essere utilizzata per rafforzare gli asset intangibili di un'azienda, rendendo unica la sua offerta. Questo aspetto è particolarmente importante tenendo in considerazione una visione basata sulle risorse, secondo la quale l'unicità delle risorse delle aziende rappresenta un importante motore di creazione di valore (Barney et al., 2001). Pertanto, gli NFT consentono alle aziende di preservare i loro segni identificativi sul mercato, attraverso il rafforzamento del copyright, garantendo in tal modo la preservazione del loro valore interno.

I manager ritengono inoltre che sia il metaverso sia gli NFT rappresentino strumenti importanti per la creazione di valore per i clienti, attraverso strategie di differenziazione che fanno leva sulla creazione di oggetti digitali. Ciò potrebbe, a sua volta, migliorare le relazioni tra i consumatori e le marche, e generare impatti positivi sui ricavi dell'azienda.

Infine, l'analisi evidenzia le principali sfide che sono legate all'adozione delle due tecnologie, e che riguardano principalmente gli investimenti, la conoscenza, le competenze e la sicurezza.

Nonostante l'enorme potenziale, i manager hanno sottolineato la sfida relativa alla mancanza di conoscenza di questi due fenomeni e il fatto che non ne sono ancora chiare le modalità di utilizzo, e ciò potrebbe limitarne la crescita nei livelli di adozione.

I risultati mostrano anche che, sebbene i manager siano disposti a investire nel metaverso e nelle soluzioni NFT, essi ritengono anche che non siano ancora tecnologie mainstream, e questo ne rende incerti i ritorni futuri sugli investimenti. Questo suggerisce che gli investimenti futuri sulle due tecnologie saranno limitati fino a quando il fenomeno non si svilupperà su scala più ampia. È interessante inoltre notare che alcuni manager hanno sostenuto che essere early adopter in questo settore potrebbe essere rischioso, mentre i late adopter potrebbero avere il vantaggio di evitare gli errori che altri avranno già commesso.

Un altro aspetto rilevante che è legato alle sfide, riguarda la conoscenza della tecnologia stessa e la necessità di competenze di alto livello per sfruttare appieno il potenziale di queste due tecnologie. I manager considerano quindi il fattore umano come un driver nell'adozione delle due tecnologie emergenti, e questo implica assegnare rilevanza alla formazione delle risorse umane al fine di aumentare la capacità organizzativa di fare leva su questa tecnologia, sfruttandone tutte le opportunità di mercato.

Implicazioni teoriche e manageriali. *I risultati dello studio forniscono importanti contributi teorici che sono legati all'accrescimento della comprensione del Web 3.0, con particolare riguardo al metaverso e agli NFT. Lo studio permette di evidenziare come si tratti di tecnologie che si confermano come rilevanti per business e che sono in grado di riconfigurare i sistemi del valore delle imprese, di essere una risorsa per la creazione di un vantaggio competitivo che fa leva sulla generazione di valore di mercato intangibile, e di cui i manager, anche quelli che operano nelle PMI si mostrano consapevoli.*

Inoltre, il lavoro contribuisce alla letteratura emergente sul metaverso e sulle NFT, fornendo indicazioni su ciò che i manager pensano e intendono muoversi rispetto alla loro adozione, identificando le opportunità ma anche gli ostacoli considerati più rilevanti all'adozione di queste tecnologie.

Il lavoro fornisce inoltre ai decisori delle indicazioni rispetto alle iniziative prioritarie che dovrebbero essere adottate per accelerare la diffusione di queste tecnologie da parte delle imprese.

Lo studio presenta rilevanti implicazioni manageriali. Infatti, i risultati dimostrano che il metaverso e gli NFT sono tecnologie con un alto potenziale di creazione di valore per le imprese, e che le imprese stesse, anche le PMI non possono ignorare. Tuttavia, la loro adozione implica un deciso impegno da parte delle imprese in termini di investimenti in abilità e competenze che sono essenziali per lo sviluppo di progetti ottimali che coinvolgono queste tecnologie.

Infine, l'avvio di progetti di metaverso e NFT, richiederà alle imprese una chiara definizione degli obiettivi strategici legati all'adozione delle due tecnologie, e l'implementazione di approcci gradualmente che potranno anche prevedere la creazione di collaborazioni con partner tecnologici esterni chiave per superare le lacune in termini di competenze e abilità interne.

Fostering high-impact innovation: empirical evidence in Europe

VALERIA SCHIFILLITI¹ ELVIRA TIZIANA LA ROCCA² MAURIZIO LA ROCCA³

Abstract

The present exploratory research paper delves into the dynamics between external and internal catalysts for innovation and their impact on the profundity of innovation within firms, integrating insights from the disruptive innovation and the resource-based view frameworks. On the one hand, the study examines market competitiveness as an external driver of innovation. On the other, it focuses on firm-level (internal) innovation drivers, particularly those related to patents. This investigation encompasses a large dataset of publicly listed European corporations over the period from 2013 to 2021. The findings indicate a positive relationship between the depth of innovation and certain innovation drivers. Nevertheless, an inverse relationship is identified between the patent's portfolio and innovation depth, suggesting that a small number of valuable patents, in comparison to the overall patent count, diminishes innovation depth. This paper proposes that future research should examine how the influence of these external and internal drivers on a firm's innovation depth varies across different sectors and explore the effect of moderating variables on the relationship studied. By offering a general view of the innovation drivers, this research enriches the existing academic literature with novel perspectives.

Keywords: *innovation drivers; innovation depth; intellectual property*

Framing of the paper. *It is widely recognized that intellectual property (IP) serves as a fundamental element for fostering innovation and attaining an advantage in the global marketplace (Coro and Burtchaell, 2021; OECD 2023). However, the rapid progression of Industry 4.0, the intricate relationship between market dynamics and the technical quality of IP becomes increasingly critical. Within this context, markets for technology not only addresses how technologies evolve and influence market dynamics but also how they are integrated into business models and marketing strategies to drive innovation and competitive advantage. Hoffman et al. (2021) emphasized the need for marketing scholars to develop theoretical paradigms that encapsulate how technologies foster competitive advantages, connecting technological innovation directly to marketing theory and practice. Mansour and Barandas (2017) contribute to the discussion by focusing on high-tech entrepreneurial content marketing and its role in business model innovation. Their study illustrates how high-tech entrepreneurs leverage innovative marketing strategies under limited resources and unpredictable conditions, underlining the connection between technology, marketing, and business model innovation. In their research on the transformative effects of marketing innovation on the competitiveness of businesses, Ungerman, Dědková, and Gurinová (2018) affirmed that the significance of innovative solutions increases the development of products and strategies in the context of Industry 4.0. Their findings indicate that firms engage in continuous innovation in response to the competitive pressures imposed by market attractiveness. As stated by Guo, Pérez-Castrillo, and Toldrà-Simats (2017) market coverage, through its influence on a firm's strategic direction, can significantly modulate the innovation quality of IP, underscoring the relevance of external market pressures in shaping IP strategies. Gök and Peker (2017) exploring how innovation performance is connected to market and financial performance, highlighted that market performance plays an important role in converting innovation into favourable financial results. Their research indicates that the attractiveness of the market not only directly influences the quality of innovation but also plays a vital role in how innovation contributes to overall corporate performance. Anand et al. (2016), adopting the framework of an innovation diffusion model, found a direct relationship between the breadth of market coverage and the success of a product in terms of diffusion and sales. In their research on the relationship between the direction, depth, and nature of openness and innovative achievement of Chinese companies, Chen et al. (2011) found that increased scope and depth of openness enhances innovative performance, suggesting that open innovation is applicable beyond science and*

technology-focused innovation. According to Yun et al. (2016) the knowledge-based economy and open innovation, are related to the interdependencies among technology, business model innovation, and market expansion.

Purpose of the paper. Innovation, which is crucial for both competitive advantage and economic expansion, is driven by a variety of elements. These drivers can be classified into two main categories: internal and external. Each of which has a substantial impact on the innovative capabilities as well as outcomes of a company. It is important for organizations seeking to create a culture of innovation and preserve a competitive advantage in rapidly changing markets to recognize these drivers. Internal drivers of innovation may include: an organizational culture that promotes risk-taking, experimentation, and the open exchange of ideas providing an ideal environment for fostering innovation. Effective leadership that encourages and advocates for innovative projects is crucial as well as transformational leadership that has been recognized as a key factor in promoting innovation (Bass, 1985). The competence, creativity, and abilities of company's employees are essential factors that inspire innovation since companies that invest in personnel development and knowledge acquisition experience increased innovation outputs (Becker, 1964). Furthermore, the Resource-Based View (RBV) theory posits that an organization's resources and capabilities, which comprise its unique competencies, financial resources, and technological assets, are pivotal catalysts for innovation (Barney, 1991). Both technological advancements and the competitive dynamics within an industry are examples of external drivers of innovation. They may encourage businesses to innovate since businesses are driven to continuously innovate as a result of the pressure, they feel to maintain their competitiveness in the context of quickly evolving technologies and industry standards (Schumpeter, 1942). Moreover, innovations are frequently driven by changing demands and preferences of consumers. According to von Hippel (1988), market demand serves as a stimulus for innovation, which allows businesses to modify their goods and services to satisfy the expectations of their customers. Also, the rules, regulations, and incentives imposed by the government can have a considerable impact on innovation. In accordance with Edquist (1997), policies that encourage research and development activities, preserve intellectual property rights, and provide support for startup ecosystems all result to increased levels of innovation. Furthermore, collaborations with universities, research institutes, and other organizations, in addition to participation in innovation networks, have the potential to significantly increase the capacity of a company to innovate since these connections allow for access to novel ideas, resources, and markets (Powell, Koput, and Smith-Doerr, 1996).

Previous scholars analysed the impact of innovation considering several aspects. Zhao (2020) provided a foundational perspective on the relationship between technology and economic behaviour, highlighting the multifaceted ways in which technology can foster economic activities while also addressing potential negative impacts on society. Coccia (2017) in the study on problem-driven innovation, especially in fields like the pharmaceutical industry, where the co-evolution of problems and solutions drives radical innovations, found that the motivation behind firms' examination of innovative solutions to unsolved problems are a means to secure competitive advantages in technologically dynamic markets. However, by integrating the Disruptive Innovation theory with the Resource-Based View (RBV), the present study explores how firms can leverage their unique resources and market conditions to foster innovation. Christensen's (1997) introduction of the Disruptive Innovation concept transformed the way in which new competitors can challenge market leaders. Rather than aiming to improve their products for the existing customer base, they may achieve so by initially concentrating on underserved segments or addressing simpler demands. Subsequently, Christensen, Raynor, and McDonald (2015) provided further elucidation on the theory by differentiating "disruptive innovations" from those that are primarily efficiency-oriented. According to Barney's (1991) RBV of the firm, organizations obtain and maintain a competitive edge by acquiring and effectively managing resources that are valuable, rare, imitable, and non-substitutable (VRIN). Intellectual property, and patents in particular, are recognized as strategic assets that organizations can utilize to foster innovation and establish a unique position in the market (Hall, Jaffe, & Trajtenberg, 2005). Significantly influencing the change in the focus from external factors to internal capabilities, the RBV has highlighted strategic asset management as a critical success factor in encouraging innovation (Wernerfelt, 1984).

Extensive research has been conducted on the relationship between market competitiveness and innovation activity, and the results support both positive and negative effects on innovation intensity. An "inverted-U" relationship between competition and innovation is proposed by Aghion et al. (2005), which posits that moderate levels of competition foster innovation, whereas excessively high or low levels may impede it. This viewpoint is supported by other scholars that emphasises the role of firms' strategic asset management, specifically with regard to patents, in mitigating these consequences, enabling companies to effectively deal with competitive pressures and taking advantage of opportunities for innovation (Teece, 1986). In recent empirical investigations, the correlation between patent strategies and innovation outcomes has been examined. For example, research has indicated that companies that possess extensive patent portfolios not only safeguard their novel ideas but also serve as an indicator of their technological prowess to the market, thereby enticing investments and collaborations (Hsu & Ziedonis, 2013). Furthermore, there is a correlation between the market value and innovation performance of companies and the quality and applicability of patents (Bessen & Meurer, 2008).

Despite the extensive body of literature on Disruptive Innovation, the RBV, and market competitiveness, few studies have synthesized these perspectives to understand how firms can navigate competitive landscapes and leverage strategic assets to achieve deep innovation. Therefore, by adopting the theoretical framework of disruptive innovation and RBV, the purpose of the present study is to analyse the impact of external and internal innovation drivers on company's innovation depth. Hence, we propose the following hypotheses:

H1: There is a positive relationship between the number of innovator competitors (market competitiveness) and innovation depth.

H2: The depth of innovation decreases as the concentration of patents' portfolio increases.

H3: The depth of innovation increases as the economic value of patents becomes more relevant.

Methodology. *Our study develops a quantitative analysis based on data collated through Orbis Intellectual Property (Orbis IP) database of Moody’s Analytics, former Bureau van Dijk. The analysis focuses on listed companies of the following European countries: Austria, Belgium, Cyprus, Denmark, Finland, France, Germany, Gibraltar, Greece, Iceland, Ireland, Italy, Luxembourg, Monaco, Netherlands, Norway, Portugal, Spain, Sweden, Switzerland, and Turkey,*

The sample includes non-financial firms, with a total of 12958 observations. An unbalanced panel covering a period from 2013 to 2021. We perform the firm-fixed effects analysis to eliminate unobservable heterogeneity with robust standard errors.

Table 1 reports a comprehensive description of the variables used in our preliminary empirical analysis.

The dependent variable is “Depth of innovation” the level or magnitude of novelty and change introduced by an innovation, valued by IPBI (<https://www.ip-bi.com>). It is related to all other companies with patents in the same branch to be fully comparable to the direct competitive environment.

Our main explanatory variables are:

- *“Market competitiveness”, as proxy of external innovation driver. It is the number of competitors that are active with innovations made in the technical fields of the company, valued by IPBI (<https://www.ip-bi.com>).*
- *“Patents portfolio”, as proxy of firm-level innovation driver. It is a measure of concentration of values across the IP portfolio, valued by IPBI (<https://www.ip-bi.com>). It measures if the value of patents’ portfolio of a firm is concentrated in a few patents or homogenously dispersed among all the patents.*
- *“Patents relevance”, as proxy of firm-level innovation driver. It is measured by the total value of patents in portfolio (valued by IPBI, <https://www.ip-bi.com>) scaled to the company’s total assets (by Orbis database).*

Traditional control variables are included in the model. Cash Holding, amount of liquidity held by the company, and Leverage are considered in our analysis as financial capital variables. Tangibility represents the firm tangible assets, and it is measured by the ratio of tangible assets to total asset. It could strengthen firms’ financial capacity since they are used as collateral. This group of financial variables can give a general idea of the firm’s financial resources that could be invested in strategic projects, such as those related to innovation. We control, also, for firm Size (natural logarithm of total assets) and firm Age (natural logarithm of number of years since the firm foundation plus one), as proxy for the reputation and track record a company gains over the years. Net Working Capital, Industry-Adjusted MtB ratio, Return on Asset (ROA), Industry-Adjusted Growth Sales are well-established firm performance measures.

Tab. 1: Description of the variables used in the analysis

Variables	Description
<i>Dependent variable</i>	
Depth of innovation	It refers to the level or magnitude of novelty and change introduced by an innovation, valued by IPBI (https://www.ip-bi.com). It is related to all other companies with patents in the same branch to be fully comparable to the direct competitive environment.
<i>Independent variables</i>	
Market competitiveness	From an intellectual property point of view, number of competitors that are active with innovations made in the technical fields of the company, valued by IPBI (https://www.ip-bi.com)
Patents portfolio	It is a measure of concentration of values across the IP portfolio, valued by IPBI (https://www.ip-bi.com). It measures if the value of patents’ portfolio of a firm is concentrated in a few patents or homogenously dispersed among all the patents.
Patents relevance	Total value of patents in portfolio (processed by IPBI - https://www.ip-bi.com) scaled to the company’s total assets (by Orbis database)
<i>Control variables</i>	
Cash Holding	Cash and cash equivalent on total assets.
Leverage	Financial debt on total assets
Tangibility	Tangible assets to total assets
Firm Size	Natural logarithm of total assets
Firm Age	Natural logarithm of number of years since the firm foundation plus one
Net Working Capital	Current assets minus short term liabilities
Industry-Adjusted MtB ratio	Firm’s MTB ratio minus two-digits industry MTB ratio. MtB is the firm’s market value of equity scaled to book value of equity.
ROA	Ratio between EBIT and total assets
Industry-Adjusted Growth Sales	Firm’s annual rate of growth of sales minus two-digits industry annual rate of growth of sales

Source: our elaboration from Orbis IP and Orbis database

Table 3 presents the correlation matrix of the variables. It does not show particularly high correlations. In addition, we assessed the potential multicollinearity among the independent variables using variance inflation factors (VIFs). The average VIF is 1.27 (max VIF=1.61), which is below the generally employed cut-off of 10 (or, more prudently, 5) for regression models (Kutner et al., 2004), suggesting that multicollinearity does not affect our results.

Tab. 3: Correlation matrix

Source: our elaboration

The variable “Market competitiveness” is positive and statistically significant. It means that as the number of innovator competitors increases (market competitiveness), the depth of innovation increases.

In column 2, the negative and statistically significant coefficient of the variable “Patents portfolio” reveals that the presence of few patents of value compared to the total number of patents decreases depth of innovation.

Concerning the variable “Patents relevance”, as the economic value of patents becomes more relevant, the level of company’s innovation increases.

Research limitations. This study is an initial exploratory analysis, a work-in-progress regarding a sample of European listed firms operating in non-financial sectors. In our future research we want to complete this analysis examining how the impact of this external and internal innovation drivers on firms’ innovation depth differs by sector and considering the role of moderating variables on the relationship studied. In this regard, more advanced econometric techniques could be useful to better understand the relationship investigated.

Managerial implications. Our preliminary findings suggest, first of all, that market dynamics, in introducing heterogeneity of firms in industries, is a core factor shaping innovation depth. Higher competitiveness in the market fosters disruptive innovation by firms in search of long-term competitive advantages. In line to what suggested by the classical work of Smith (1776), named the “escape effect”, market competitiveness generates greater incentives to firms to develop innovative processes. Innovators could successfully escape competition in the long-run by gaining a competitive advantage and a certain degree of future market power. Thus, competition boosts higher level innovation.

In a similar vein, it results a sort of path dependence in innovation. Firms having higher value of patents, a track record of success in high impact patenting, are the one that are able to innovate at most.

Finally, it results that if the value of innovation is concentrated in a few patents, a low number of patents provides the vast majority of patent value. Specialization, to have a focus on specific knowledge, is at the core of greater advancement in research and innovation of higher prominence.

Competitiveness, when coupled with a strategic approach to intellectual property management, significantly enhances the technical depth of innovations. These findings contribute to the broader discourse on innovation management, offering insights into the mechanisms through which firms can sustain competitive advantage in dynamic markets.

From a managerial point of view, this research offers practical insights for managers on leveraging intellectual property and aligning innovation strategies with market conditions to foster sustainable competitive advantage.

From a policy point of view, regulations that promote equal competition may encourage the admission of new firms into markets and the introduction of innovative products and processes, subsequently impacting market structures.

The research indicates that companies tend to provide more innovative solutions when operating in a competitive environment that fosters a culture of innovation and offers valuable perspectives into the innovative behavior of European companies.

Originality of the paper. This present research contributes to the existing body of literature on innovation management by providing empirical evidence on internal and external innovation drivers that affect company innovation depth. The analysis is developed using variables and measures in line with the literature which represent a novelty for the research stream on Innovation depth. The key contributions of the paper are threefold. First, we conduct an empirical examination of the significance of three distinct categories of innovation drivers, namely market competitiveness, patent portfolio, and patent relevance (as in Table 1). Second, we differentiate between drivers that are sourced internally or externally. Finally, the effect of these variables on the depth of innovation is evaluated, regardless of whether the innovation is incremental or radical. Overall, the findings contribute to the theoretical discourse on innovation management, emphasizing the synergy between competitive strategies and intellectual property management in fostering innovation. This research framework underscores the complexity of innovation processes, highlighting the interdependencies between market forces, strategic assets, and firm capabilities in shaping innovation trajectories.

Innovation in I4.0 and firms performance in Italy

FRANCESCO CAPONE¹ NICCOLÒ INNOCENTI² LEONARDO MAZZONI³ LUCIANA LAZZERETTI⁴

Abstract

This paper addresses the substantial debate surrounding Industry 4.0 (I4.0) and its impact on techno-economic systems, capturing the attention of business managers and policy-makers. Despite the acknowledged influence of I4.0 on firms, countries, and clusters, empirical assessments at the firm level have been scarce. The study aims to fill this gap by investigating the link between innovation in I4.0 technologies and firm performance.

The research underscores the dual benefit of I4.0 innovation—enabling technological solutions within enterprises and ensuring market success. Grounded in the idea that firm-developed knowledge influences economic performance, the study conducts a long-term analysis based on patents related to I4.0 from Italian companies (2010-2019). The central question revolves around the impact of I4.0 innovation on firm performance.

Using patents as an innovation proxy, the study examines spillovers on business and market performance, focusing on new knowledge and innovation processes in I4.0 technologies. Employing EPO's (2017) methodology, it identifies I4.0 patents from Italian inventors and correlates them with firm-level information from the AIDA Bureau van Dijk database.

Results from scatter-plots and regression analysis, reveal a positive relationship between patent generation in I4.0 and firm performance. This correlation remains stable across periods and performance indices, albeit within a predominantly large enterprise sample. The study contributes valuable insights to the discourse on the tangible effects of I4.0 innovation at the firm level.

Key words: Innovation, Industry 4.0, patents, firms' performance

Framing of the research. *The contemporary discourse surrounding Industry 4.0 (I4.0) has engendered a widespread and intricate debate within the academic and industrial spheres. The I4.0 paradigm, which integrates digital technologies with traditional industrial processes, has become a focal point of discussion, garnering substantial attention from business managers and policy-makers alike. The literature reflects a comprehensive exploration of the profound impact that I4.0 can exert not only on individual firms but also on broader techno-economic systems, spanning nations, regions, clusters, and industrial districts (Piccarozzi et al., 2018).*

This burgeoning body of work underscores the transformative potential of I4.0, tracing its roots back to the coining of the term by Kagerman et al. (2011). The literature has consistently emphasized the considerable influence I4.0 can wield (BCG, 2015; Capone and Innocenti, 2023; Capone et al., 2023; Mariani and Borghi, 2022; Piccarozzi et al., 2018). Beyond its impact on individual enterprises, the discourse extends to the macroeconomic level, examining the effects on countries and regions (Hervás Oliver et al. 2021; Götz & Jankowska, 2017).

However, despite over a decade of exploration since the inception of the I4.0 concept, a notable gap in the literature persists. While there is a growing body of empirical studies assessing the overall phenomenon, the focus has predominantly centered on adoption, development, and implementation of I4.0 technologies (Mariani and Borghi, 2022; Bettiol et al., 2021; Capestro et al., 2022; Cirillo et al., 2023). This concentration, while valuable, has been relatively silent regarding the impact of I4.0 technology at firm level. Benassi et al. (2022) and Raj and Seamans (2018) emphasize the scarcity of empirical evidence and the need for enterprise-level data on I4.0 and AI-related technologies.

In response to this gap, this paper positions itself within the broader discourse to explore the firm-level implications of I4.0 technology implementation. It aligns with Benassi et al. (2022) observe that empirical evidence in this domain is sparse (Cirillo et al., 2023; Bettiol et al., 2023a, b). By delving into the relationship between innovation in I4.0 technologies and firm performance, the research seeks to contribute nuanced insights to this ongoing debate, shedding light on unexplored dimensions of the I4.0 paradigm's impact on techno-economic systems.

Purpose of the paper. *The primary objective of this research is to make a substantial contribution to the ongoing discourse surrounding the impact of Industry 4.0 (I4.0) innovation on firm performance.*

Specifically, the study seeks to investigate the link between innovation in I4.0 technologies and the subsequent performance of firms. The aim is to shed light on how the ability to produce innovation in the context of I4.0 can catalyze a twofold benefit for organizations. Firstly, it aims to discern the impact on firms' internal processes, including the implementation of technological solutions and the initiation of product/process innovations. Secondly, it aims to investigate the external ramifications, focusing on the ability of firms to commercialize these technological solutions in the market successfully.

Given the acknowledged scarcity of empirical evidence on the firm-level impacts of I4.0 technology implementation, the research aims to address this gap by conducting a comprehensive and longitudinal analysis. The chosen timeframe spans from 2010 to 2019, allowing for a thorough examination of the sustained effects of I4.0 innovation on both business and market performance.

Building on existing studies, notably the work by Benassi et al. (2022) that establishes a positive correlation between innovation in I4.0 and firm productivity, this research aspires to extend the inquiry further. The focus is not solely on immediate productivity gains but on assessing whether the spillovers of innovation in I4.0 can manifest in enduring positive impacts on business performance.

The research utilizes a robust methodology, leveraging patents as a proxy for innovation, to measure the development of knowledge and skills over time. By concentrating on patents related to I4.0 developed by Italian companies, the study endeavors to capture a nuanced understanding of the intricate relationship between innovation production in I4.0 and subsequent firm performance.

In summary, the overarching aim of this research is to provide nuanced insights into the firm-level implications of I4.0 innovation. Through a rigorous analysis of patents and firm-level data, the research seeks to contribute valuable knowledge to both academic discussions and practical considerations for businesses navigating the dynamic landscape of Industry 4.0.

Methodology. *This study employs a quantitative methodology to investigate the link between innovation in Industry 4.0 (I4.0) technologies and firm performance. Building on existing literature gaps, our approach integrates patent analysis, longitudinal examination, and firm-level data exploration.*

Firstly, the study focuses on patents related to I4.0 technologies developed by Italian companies during the period 2010-2016. Patents serve as a key indicator of innovation, offering a tangible measure of firms' commitment to I4.0 advancement. The choice of patents as a proxy aligns with established methodologies in innovation studies (Griliches, 1990).

To assess the influence of I4.0 innovation on company performance, the study adopts a long-term analysis, spanning the period from patent development (2010-2015) (patents realized in the period 2010-2015 with depreciated rate by 10%) to subsequent years before the pandemic (2017-2019) (See Figure 1 and Table 1). This temporal extension allows for a nuanced understanding of the enduring effects of I4.0 innovation on firm performance over time.

Furthermore, the research employs a dual-level data collection process. Initially, patents in I4.0 technologies made by Italian inventors and applicants are identified using the methodology established by the European Patent Office (EPO) in 2017. Subsequently, firm-level information for each patent applicant is extracted from the AIDA Bureau van Dijk database. This comprehensive dataset integration ensures a robust exploration of the relationship between I4.0 patents and firm performance.

By employing statistical analysis, scatter-plots and regression techniques, the study aims to unveil the patterns and relationships between the ability to generate patents in I4.0 and firm performance. Notably, this analysis goes beyond a mere correlation assessment; it delves into the nuances of the relationship, ensuring a nuanced understanding of the impact of I4.0 innovation on various performance indices.

Results. *The study establishes a positive correlation between the production of innovation in Industry 4.0 (I4.0) technologies and the overall performance of companies in Italy (Figure 1 and Table 1). These findings align with similar research (Benassi et al., 2022; Cirillo et al., 2023). Unlike Benassi et al. (2022), who attributed inconclusive results to a relatively short analysis period, our longitudinal study, spanning from 2010 to 2019, captures the link between I4.0 innovation and economic performance, providing a more comprehensive understanding.*

However, specific considerations deserve attention. The sample selection process predominantly focuses on companies exhibiting intense patenting activities at the European level, directing the analysis towards large enterprises. This strategic choice inadvertently limits the representation of smaller entities. The study recognizes the absence of insights from small and medium-sized enterprises (SMEs) and acknowledges the necessity for future research to bridge this gap, providing a more holistic view of the diverse business landscape.

Moreover, the study has endeavored to address issues of reverse causality by incorporating a significant temporal lag between variables. It is essential to acknowledge that certain outcomes align with prior research, as evidenced by Benassi et al. (2022), emphasizing that 98% of I4.0 patents in Europe originate from large enterprises.

The preliminary analysis underscores the impact of company size, revealing a positive correlation between all variables and firm size, measured in terms of both employees and revenue. This nuance underscores the importance of delving into the perspectives of SMEs, warranting future studies to address this aspect comprehensively.

In conclusion, despite the acknowledged considerations, this paper adds a meaningful dimension to the ongoing discourse on the impact of I4.0 technologies on business performance. The study prompts further scientific exploration,

both theoretically and methodologically, offering compelling insights and laying the groundwork for future developments in this evolving research domain.

Research limitations. While the study provides valuable insights, it is essential to acknowledge and elaborate on certain limitations that may influence the interpretation and generalizability of the findings.

Firstly, the reliance on patents as a sole proxy for innovation introduces a potential limitation. Patents predominantly capture a specific type of innovation and may not fully encompass the broader spectrum of innovative activities within organizations. It is conceivable that some innovative endeavors, particularly those in the rapidly evolving landscape of Industry 4.0 (I4.0), might not be adequately represented through the patent data. Thus, the study's focus on patents may inadvertently underestimate certain non-patentable innovations or collaborative efforts that contribute significantly to firm performance.

Moreover, the study's geographical focus on Italian inventors and applicants may restrict the generalizability of findings to a more global context. Different regions may exhibit distinct innovation ecosystems, regulatory environments, and market dynamics, influencing the relationship between I4.0 innovation and firm performance. Thus, caution is warranted when extrapolating these findings to other countries or international settings.

The composition of the sample, predominantly comprising large enterprises, introduces a potential sample bias. The findings may not fully capture the dynamics and challenges faced by small and medium-sized enterprises (SMEs) in

adopting and benefiting from I4.0 innovations. SMEs often operate under resource constraints and may face different barriers to innovation compared to their larger counterparts. Future research should explore these nuances to provide a more comprehensive understanding of I4.0's impact across diverse organizational sizes.

The temporal scope of the study, covering the years 2010 to 2019, may introduce limitations in capturing the most recent developments in the I4.0 landscape. Given the rapid evolution of technology, the study's insights may not fully reflect the current state of I4.0 adoption and innovation strategies. Therefore, the findings should be interpreted with a consideration of the evolving nature of the I4.0 paradigm.

Additionally, the study focuses on the relationship between I4.0 innovation and firm performance without delving into potential mediating or moderating factors. Future research could explore contextual elements, such as organizational culture, leadership styles, or external market conditions, to offer a more nuanced understanding of the mechanisms influencing this relationship.

In conclusion, while the study contributes significantly to the discourse on I4.0 innovation and firm performance, researchers and practitioners should interpret the findings within the context of these limitations. Addressing these limitations in future research endeavors will further enrich our understanding of the complex dynamics surrounding the impact of I4.0 on organizational outcomes.

Managerial implications. The study's findings offer valuable insights with direct implications for managerial decision-making in the context of Industry 4.0 (I4.0) adoption and innovation strategies.

Firstly, the positive correlation identified between the ability to generate patents in I4.0 technologies and firm performance underscores the strategic importance of fostering an innovative culture within organizations. Managers should actively encourage and support initiatives that promote innovation in I4.0, recognizing it as a driver of enhanced performance metrics. This involves dedicating resources to research and development activities specifically focused on I4.0 technologies.

Moreover, the dual benefit highlighted in the study, whereby innovation in I4.0 not only improves internal processes but also contributes to market success, emphasizes the need for a holistic approach. Managers should aim to align innovation efforts with both internal operational enhancements and external market competitiveness. This may involve developing products or solutions that are not only technologically advanced but also resonate with market demands and trends.

Furthermore, the findings suggest that a proactive approach to innovation in I4.0 can contribute to sustained firm performance over time. Managers are encouraged to view innovation not as a one-time effort but as an ongoing process. Long-term planning and investment in I4.0 technologies may yield spillover effects that positively impact business and market performance.

In conclusion, the study's managerial implications call for a strategic focus on fostering innovation in I4.0 technologies, aligning internal and external goals, securing intellectual property, and adopting a long-term perspective. Embracing these implications can position organizations at the forefront of the dynamic I4.0 landscape, driving sustained success and competitiveness.

Originality of the paper. This study significantly contributes to the existing body of literature by offering novel perspectives and addressing gaps in the understanding of the relationship between Industry 4.0 (I4.0) innovation and firm performance. Several aspects underscore the originality of this research.

Firstly, the study navigates uncharted territory by focusing on the firm-level impact of I4.0 technology implementation. Despite the extensive literature on I4.0, empirical examinations at the organizational level remain scarce. By specifically investigating the link between innovation in I4.0 technologies and firm performance, the study ventures into a critical area that has received limited attention to date.

Secondly, the temporal dimension adds a distinctive layer to the research's originality. While the I4.0 paradigm has been under scrutiny for over a decade, this study bridges the gap between the initial years following its conceptualization and a subsequent period, providing a longitudinal perspective. This temporal depth allows for a nuanced understanding of the enduring impact of I4.0 innovation on firm performance, providing insights that extend beyond immediate effects.

Furthermore, the choice of patents as a proxy for innovation introduces a methodological innovation to the study. Patents serve as tangible indicators of firms' commitment to I4.0 innovation and provide a measurable metric for knowledge and skill development over time. This methodological choice not only aligns with the study's objectives but also contributes to the methodological toolkit available for investigating the impact of emerging technologies on organizations.

The incorporation of an Italian context into the analysis also enhances the originality of the study. By focusing on patents developed by Italian inventors and applicants, the research acknowledges the importance of considering regional and national contexts in understanding I4.0 innovation dynamics. This contextual specificity contributes to the richness of the findings and facilitates a more nuanced interpretation of the relationship between I4.0 innovation and firm performance.

In summary, the originality of this paper lies in its targeted exploration of firm-level impacts of I4.0 innovation, the longitudinal perspective it adopts, the methodological innovation in using patents as a measure of innovation, and the contextual richness introduced through the focus on the Italian landscape. These elements collectively position the study as a distinctive and valuable contribution to the evolving literature on I4.0 and its implications for organizational outcomes.

The “5Vs” of Big Data and the Propensity to Generate Patents with Big Data Technologies in SMEs

ENRICO MARCAZZAN¹ SAVERIO BARABUFFI² GIULIO FERRIGNO³ ANDREA PICCALUGA⁴

Abstract

In the contemporary digital landscape, the exponential growth of data, commonly referred to as Big Data, has become indispensable for businesses worldwide. Understanding the fundamental characteristics of Big Data, encapsulated by the “5Vs” (Volume, Variety, Velocity, Veracity, and Value), is crucial for deriving value and fostering innovation. This research explores the nexus between these “5Vs” and the propensity of Small and Medium-sized Enterprises (SMEs) to generate patents based on Big Data technologies. The study employs a knowledge-based view (KBV) framework to investigate this relationship, focusing on Italian SMEs. Through a questionnaire-based survey involving 135 SMEs, the research analyzes the impact of each of the “5Vs” on the generation of patents with Big Data technologies. The methodology utilizes multinomial probit analysis to assess the likelihood of developing different levels of patents in relation to the “5Vs” of Big Data. Findings suggest that while the “Variety” of data positively influences SMEs’ propensity to generate patents, other factors such as “Volume”, “Velocity”, “Veracity”, and “Value” show varying degrees of significance. Notably, the study reveals a counterintuitive relationship where a higher volume of data impedes SMEs’ patent generation activities. Similarly, factors like real-time data processing speed, data quality, and value extraction from Big Data show no significant impact on patent generation. This research underscores the importance of understanding the nuanced interplay between different dimensions of Big Data and innovation outcomes, particularly for SMEs. The findings suggest that SMEs should prioritize enhancing the diversity and sources of their data over sheer volume or speed of processing. Moreover, the study emphasizes the need for SMEs to consider the potential “dark side” effects of Big Data, advocating for a shift towards leveraging “Smart Data” rather than focusing solely on Big Data. In conclusion, this work contributes novel insights by highlighting the complex relationship between the “5Vs” of Big Data and SMEs’ patent generation activities. The findings offer valuable guidance for SMEs seeking to navigate the digital landscape effectively, innovate, and maintain competitiveness in the market.

Key words: big data; patents; SMEs.

Framing of the research. *In the digital age in which we live, the amount of data generated every day is growing exponentially (Cappa et al., 2021). This immense amount of data, commonly known as Big Data, has become an invaluable resource for businesses and institutions around the world (Ferrigno et al., 2023). Specifically, by Big Data we mean “any set of data that, with traditional systems, would require large capabilities in terms of storage space and time to be analyzed” (Del Vecchio et al., 2018, p. 6). However, managing, analyzing and deriving value from this mass of information requires not only advanced technological tools, but also a thorough understanding of its fundamental characteristics, the so-called “5Vs”: Volume, Variety, Velocity, Veracity and Value (Acciarini et al., 2023). “Volume” refers to the amount of data (Ghasemaghahi and Calic, 2019). With the advent of the Internet of Things (IoT), social media, and other digital devices, the volume of data has exploded to unprecedented levels. This enormous flow of information offers endless opportunities for analysis and innovation. “Variety” refers to the different types of data collected and processed by an enterprise (Ghasemaghahi, 2021; Pedota, 2023). This diversity includes text, images, audio, video, and more. The ability to integrate and analyze a wide range of data is critical to fully understand the context and gain meaningful insights for firms’ R&D activities (Ferrigno et al., 2023). The “Velocity” of Big Data refers to “the speed and the frequency of processing and integrating data” (Ghasemaghahi and Calic, 2020, p. 150; Ghasemaghahi et al., 2017). With the world becoming increasingly connected and real-time, the ability to analyze data in real time becomes essential to seize immediate opportunities and make informed decisions. “Veracity”, on the other hand, is defined as*

¹ Sant’Anna School of Advanced Studies, Pisa

⁴ Sant’Anna School of Advanced Studies, Pisa
e-mail: andrea.piccaluga@santannapisa.it

“reliability and credibility of data” (Ghasemaghaei and Calic, 2019; p. 73). Data quality is critical to ensure that analyses and decisions based on them are valid and reliable. Verification and management of data quality are therefore crucial in any analysis process. The fifth V, “Value”, refers to “firm’s ability to create value from big data” (Cappa et al., 2021, p. 53; Ghasemaghaei, 2021). In this sense, the value of Big Data is not intrinsic, but depends on the ability to interpret and use the data effectively to achieve desired goals.

The potential of Big Data has taken a central role in the development and growth of not only large organizations but also small and medium-sized enterprises (SMEs) (Vitale et al., 2010). SMEs are a key pillar of the global economy, contributing significantly to innovation and value creation (Müller et al., 2017). Understanding the relationship between the “5Vs” of Big Data and the propensity of SMEs to generate patents based on Big Data technologies is crucial to take full advantage of the opportunities offered by this digital revolution (Del Vecchio et al., 2018). Specifically, the importance of relying on patents stems from the fact that they can be valid measures of innovation and, when related to Big Data technologies, excellent measures to better understand the evolution of Big Data technologies (Saheb and Saheb, 2020). In addition, specifically for SMEs, patents can be considered as valid predictors of business performance (Müller et al., 2017).

Purpose of the paper. The purpose of the present “work-in-progress” is to understand which “Vs” have the greatest impact on the propensity to generate patents with Big Data technologies, considering the fact of the potential “dark side” effects of Big Data (Cappa et al., 2021). Through the lens of the knowledge-based view (KBV, Grant, 1996), the present research work aims to address the following research question:

RQ: Which Vs of Big Data have an impact on the generation of patents based on Big Data technologies in SMEs?

To address this research question, we give below some reasons for the relationship between “5Vs” and the propensity to develop patents on big data.

Volume

The huge volume of available data offers multiple opportunities for innovation in various sectors (Cappa et al., 2021), including for SMEs (Del Vecchio et al., 2018). Companies can develop new technologies and solutions based on Big Data to improve their products, services, or operational processes, resulting in new ideas (Johnson et al., 2017) that can be protected through patents. In a competitive environment, access to big data can provide a significant strategic advantage (Ghasemaghaei and Calic, 2019; Ghasemaghaei, 2021). Firms that can effectively exploit the volume of available data can develop innovative and advanced solutions that set them apart from competitors, potentially leading to patents for their distinctive technologies. Nonetheless, managing large volumes of data can be expensive (Cappa et al., 2021; CoalaData, 2014; Trabucchi et al., 2017), especially for SMEs that are characterized by resource scarcity. As suggested by recent empirical work, the role of “Volume” on business outcomes may be characterized by non-significance (Ghasemaghaei, 2021; Ghasemaghaei and Calic, 2019) or even negative effects (Cappa et al., 2021). In line with the above, our first hypothesis is as follows:

H1: Volume is negatively correlated with the propensity to develop patents with big data technologies.

Velocity

The speed at which data are generated and analyzed can affect a company’s ability to adapt quickly to changing market conditions (Ghasemaghaei and Calic, 2019). Technologies that enable real-time data processing and analysis can be invaluable in developing innovative solutions that improve operational efficiency or the ability to respond promptly to customer needs.

The ability to rapidly collect and analyze data can enable companies to identify emerging trends, market opportunities, or potential problems (Johnson et al., 2017). Technological solutions that facilitate this responsiveness can be patentable, thus protecting the firm’s investment in these advanced capabilities. Moreover, in a rapidly changing environment, the speed at which data become obsolete is a critical factor (D’Aveni et al., 2017; Johnson et al., 2017). Companies that develop technologies to manage and analyze large volumes of data in real time can reduce the risk of information obsolescence and gain a competitive advantage. These innovative solutions can be patented to protect their uniqueness and value. In line with the above, our second hypothesis is as follows:

H2: Velocity is positively correlated with the propensity to develop patents with big data technologies.

Variety

The diversity of data types available requires innovative solutions to effectively integrate and analyze all these sources of information (Ghasemaghaei and Calic, 2020). Companies that develop technologies to manage the variety of Big Data extract value from this diversity can gain a competitive advantage. These solutions may be subject to patenting to protect their intellectual property.

Different types of data require specific analytical approaches to extract meaningful information. Companies that develop innovative algorithms or methodologies to analyze heterogeneous data can gain a competitive advantage (Ghasemaghaei, 2021). These solutions can be patented to protect their uniqueness and ensure a return on R&D investment. Moreover, the variety of Big Data provides opportunities to customize services and offerings to the specific

needs of customers (Johnson et al., 2017). Companies that develop technologies to collect, integrate, and analyze data from multiple sources can offer highly personalized services that increase customer satisfaction and loyalty. These innovative solutions may be subject to patenting to protect their intellectual property and maintain a competitive advantage in the market. In line with the above, our third hypothesis is as follows:

H3: Variety is positively correlated with the propensity to develop patents with big data technologies.

Veracity

Data quality and reliability are crucial to obtaining accurate and meaningful results from Big Data analysis (Cappa et al., 2021). Companies that develop technologies to assess and improve the veracity of data can gain a competitive advantage. These solutions may be subject to patenting to protect their intellectual property and ensure customer confidence in the results of data analysis. Data “Veracity” can be compromised by cybersecurity threats, such as unauthorized access, data breaches, or manipulation (Brook, 2019). Companies that develop technologies to protect the veracity and integrity of sensitive data can gain a competitive advantage. These innovative solutions may be subject to patenting to protect their intellectual property and ensure the security of customer information. Moreover, much of Big Data is unstructured data, such as text, images, or video. Managing and analyzing this information effectively requires innovative solutions (Ghasemaghaei and Calic, 2020). Companies that develop technologies to extract value from unstructured data can gain a competitive advantage. These solutions may be subject to patenting to protect their intellectual property and ensure a return on R&D investment.

H4: Veracity is positively correlated with the propensity to develop patents with big data technologies.

Value

Extracting value from Big Data through data analysis and interpretation can enable companies to identify new market opportunities, optimize business operations, and improve customer satisfaction (Cappa et al., 2021; Ghasemaghaei, 2021). Innovative technologies that harness the value of Big Data may be subject to patenting to protect their uniqueness and ensure a competitive advantage in the marketplace.

Using Big Data to optimize business processes, reduce costs, and improve operational efficiency can generate significant savings and competitive advantages (Brynjolfsson et al., 2011; Ghasemaghaei, 2019; Tambe, 2014). Companies that develop technologies to extract value from Big Data and improve their internal operations can gain a competitive advantage. These innovative solutions can be patented to protect their intellectual property and ensure a return on their R&D investment. Moreover, using Big Data to better understand customer needs and preferences can enable businesses to offer highly personalized services and improve customer satisfaction (Cappa et al., 2021; Johnson et al., 2017). Innovative technologies that allow Big Data to be analyzed and used to personalize services may be subject to patenting to protect their uniqueness and ensure a competitive advantage in the market.

H5: Value is positively correlated with the propensity to develop patents with big data technologies.

Methodology. We collected the data of 135 Italian SMEs by submitting a questionnaire to gather information and data on both the Big Data characteristics, the patents with Big Data technologies done by the SME and other firm’s characteristics. More specifically, to analyze the relationship among the “5Vs” of Big Data and the propensity to generate patents with Big Data technologies in SMEs, we propose a multinomial probit (Keane, 1992; McCulloch and Rossi, 1994). since our dependent variables (“patents generated through Big Data Technologies”) is a categorical variable (in line with Messeni Petruzzelli et al., 2022). “Patents generated through Big Data Technologies” is subdivided into 4 classes: 1) “no patents”; 2) “1 patent”, 3) “between 2 and 4 patents”; 4) “more than 4 patents”. Then, we introduce as independent the 5 characteristics of Big Data: “Volume”, “Velocity”, “Variety”, “Veracity”, and “Value” which are operationalized according to a 7-point Likert scale. Then, we control for firm characteristics, such as “age”, “revenues”, “size”, and for regional and sectoral effects by introducing the dummy variables “region”, and “high technological sector”.

Results. By performing the econometric analysis, we estimate the likelihood of developing “1 patent”, “between 2 and 4 patents”, and “more than 4 patents” generated through Big Data Technologies with respect to none. Our preliminary analysis shows that “Volume” has a negative relationship for the category “1 patent” and “between 2 and 4 patents”, while it does not have any statistically significant effect on “more than 4 patents”. Then, we find that “Variety” has a positive and statistically significant effect on the category “between 2 and 4 patents”, and “more than 4 patents”. For the variables “Velocity”, “Veracity”, and “Value”, we do not find any statistical support for the three categories of patents, meaning that these Big Data characteristics do not have a statistically significant relationship with developing patents generated through Big Data technologies. We can conclude that we find support for our hypothesis H1 and H3, but not for H2, H4, and H5. The huge volume of data hinders the SMEs’ propensity of developing patents generated through Big Data Technologies, meaning that managing large volumes of data is expensive for SMEs (Cappa et al., 2021). However, managing the diversity of available data and sources improves the SMEs’ innovation performances and helps them maintain a competitive advantage in the market. Hence, SMEs can leverage the

heterogeneity of their data to improve their position in the innovative landscape and gain market power by protecting their intellectual property through patenting.

Research limitations. Our “work-in-progress” is characterized by some limitations. First, the research aims to investigate the relationship between the “5Vs” of Big Data and the propensity to generate patents with Big Data technologies individually, without investigating any internal relationships among the “5Vs”. Second, we focus only on patents with Big Data technologies as the dependent variable, without testing the impact of these patents on business performance. Third, our hypotheses are based on “correlation” between variables, without necessarily investigating “causal” relationships. These three main limitations open up insights for possible future research on the topic. In this sense, further research could find important interrelations between the “5Vs”, their effects on the business performance through patents with Big Data technologies, and “causal” relationships.

Managerial implications. Our work has several implications for SMEs. The “5Vs” of Big Data and their correlation with SMEs’ propensity to generate patents are key elements in ensuring success and competitiveness in today’s business landscape. Companies that understand and fully exploit the potential of Big Data can gain significant advantages and contribute significantly to innovation and economic growth. In this sense, instead of focusing on Big Data “Volume”, “Velocity”, “Veracity” and “Value”, SMEs should focus on improving the degree of “Variety” of Big Data. In this sense, SMEs should invest in the number of sources of big data.

Originality of the paper. The main originality of our “work-in-progress” relies on the fact that, as suggested by Plantec et al. (2023), we focus on data characteristics (i.e., “5Vs”) instead of technology (e.g., artificial intelligence) offering a complementary view of Plantec and colleagues’ work of the innovative activities of the firms. Moreover, the paper contributes to highlight the fact that Big Data are not good by themselves, but there are some “dark side” effects that must be taken into consideration adopting them. In this sense, our research suggests that it is better to rely on “Smart Data” rather than Big Data.

In conclusion, our paper presents counterintuitive findings. First, generally speaking, it is common to think that SMEs can effectively manage and analyze this huge volume of data in order to have a significant competitive advantage. However, our results suggest that higher “Volume” of data can have negative effects on the propensity to generate patents with Big Data technologies. Therefore, SMEs should focus on other “Vs” instead of the first (i.e., “Volume”). Second, in general terms, SMEs that can react quickly to market changes and emerging trends, supported by real-time analysis of Big Data (i.e., “Velocity”), can develop innovative solutions that merit patent protection. However, our research shows that it does not have a significant effect on the propensity to generate patents with Big Data technologies. Third, SMEs that invest in accurate data collection and management (i.e., “Veracity”) can develop solutions based on reliable information, increasing the credibility of their inventions and the likelihood of obtaining patents. However, our results show that it has no significance. Fourth, the concept of “Value” emphasizes the importance of turning data into meaningful information and creating tangible value for the business and customers. However, based on the results of our study, big data patents are not influenced by SMEs’ identification and exploitation of the inherent value of Big Data. Finally, only SMEs that synergistically integrate and analyze these different types of data (i.e., “Variety”) can develop innovative, multidimensional solutions that are patentable. The “Variety” dimension represents the only positive and significant factor for our results.

How WEIRD is Social Innovation? Exploring the Evolution of Social Innovation Research

JORDANA RECH GRACIANO DOS SANTOS¹ IAN MCCARTHY²

Abstract

This paper examines the extent to which empirical studies on social innovation are conducted in WEIRD (Western, Educated, Industrialized, Rich, and Democratic) countries and authored by WEIRD researchers. Through a systematic literature review, we analyzed 197 empirical research papers published in top-ranked journals in innovation, strategy, and management. We map the evolution of social innovation study locations, finding that the field has become less WEIRD over time. The analysis of articles reveals a trend towards adopting diverse country contexts, including areas previously overlooked such as countries in Africa, Latin America, and Asia. However, research is still predominantly produced by WEIRD researchers located in the United States, United Kingdom, France, and Spain. Additionally, it was found that the Journal of Business Research serves as the primary source for empirical studies within the field of social innovation, encompassing a diverse range of geographical locations in its articles.

Key words: social innovation; WEIRD context; systematic review; place; context

Framing of the research. *Businesses, organizations, and government actors are increasingly called upon to play a pivotal role in addressing these complex issues and focus on their purpose besides profit (Weerawardena et al., 2021). Social innovation has emerged as a key focus area for addressing these complex social problems, such as poverty, inequality, environmental issues, and community problems (Seelos and Mair, 2017; Santos, 2015).*

Defined by Beckman, Rosen, and Painter (2023) as novel processes or products aimed at generating effective solutions to complex social problems for collective benefit, social innovation is intricately tied to specific contexts, social relations, and institutions (Montgomery & Mazzei, 2021). Its rise in scholarly discourse is significant, reflecting a bigger shift towards confronting societal grand challenges—massive global issues spanning social and environmental domains with far-reaching implications beyond national borders (George et al., 2016; Whiteman et al., 2013).

Despite social innovation's emergence as a vital research field aimed at understanding and resolving complex societal issues, neglecting the spatial and contextual nuances can potentially trap the field (Beckman, Rosen, & Painter, 2023). Furthermore, there exists an intriguing tension in scholarly discourse regarding the positive impact of social innovation and its current application across various institutions such as academia, communities, and governments. Notably, articles within managerial settings often lack geographic specificity, with 83.62% of them failing to specify or limit their geographical locations (Beckman, Rosen, & Estrada-Miller, 2023).

Moreover, a comprehensive analysis necessitates examining multiple geographical contexts, rather than solely relying on convenient or WEIRD (Western, Educated, Industrialized, Rich, and Democratic) country data (Henrich, Heine, & Norenzayan, 2010). The term "WEIRD" describes research contexts in social science studies, particularly in experimental behavior research, where findings are often generalized as universally applicable (Henrich, Heine, & Norenzayan, 2010; Pitesa & Gelfand, 2023). As highlighted by Pitesa and Gelfand (2023), much of the scientific knowledge regarding human behavior pertains to WEIRD populations, produced by WEIRD researchers addressing WEIRD problems.

In this puzzle, our goal is to analyze the current state of the research field on social innovation and to what extent empirical studies on social innovation are done in WEIRD (Western, Educated, Industrialized, Rich, and Democratic) countries and carried out by produced WEIRD researchers.

Purpose of the paper. *To clarify this tension, this paper presents results of a systematic literature review that aimed of mapping out the samples where the studies on social innovation are being made, specifically addressing the following research question: "How WEIRD is research in social innovation?". The method involves a systematic review of seven top-ranked journals in the field of innovation and management, resulting in 197 empirical research papers.*

This paper also expects to make several contributions. First, add to the literature an evolutionary analysis of what theories are most often employed in conceptualizing and analyzing social innovation, and how do they contribute to our understanding of its processes. Secondly, analyze the context of social innovation across various geographical locations (place) and understand the development of the focus of the field over the years. Different than the article of Arnett (2008),

¹ LUISS University
e-mail jrech@luiss.it - Ian McCarthy

² e-mail: ian_mccarthy@sfu.ca

where the researcher analyzed the degree of American and international representation in major journals of the American Psychological Association (APA), this study is focused on the empirical setting in a managerial setting (innovation, management, and entrepreneurship) and institutional (geography, cultural, etc.) These findings will contribute to the context of social innovation in different countries, helping the government and individuals to understand the different relationships. As Alley and Cortina (2023) confirmed that when we imply that the results for the WEIRD sample are going to be the same explanation of the non-WEIRD, the knowledge itself can take a turn about the relationship of the variables.

Methodology. Our methodology for conducting this study was carefully crafted to ensure rigor and comprehensiveness and it was initiated by clearly defining our aims and objectives. A systematic literature review is anchored in common principles guided by a research question and a systematic approach (Gough, Thomas, and Oliver, 2019; Rojon et al., 2021). These principles aim to ensure transparency, explanatory depth, inclusivity, and a heuristic approach, as Baxter, Trott, and Ellwood (2023) outlined.

Our systematic review focused on the academic landscape of social innovation literature, exploring articles from thirteen journals without restricting the publication year. The selected journals, namely *Academy of Management Journal*, *Journal of Business Ethics*, *Journal of Business Research*, *Organization Science*, *Research Policy*, *Administrative Science Quarterly*, *Strategic Management Journal*, *Journal of Product Innovation Management*, *Entrepreneurship Theory and Practice*, *Journal of Business Venturing*, *Strategic Entrepreneurship Journal*, *Journal of Management Studies*, *Business Ethics Quarterly*. The journals were chosen based on the top journals from the Chartered Association of Business Schools (ABS) ranking, with the highest score of 4 on the field of innovation, management, and entrepreneurship and journals with the score 3 in the ranking, where they are also present in the list of Top50 Sources from Financial Times (FT), as *Journal of Business Ethics* and *Journal of Business Research*.

For the source of our study, it was used Scopus, as a renowned multidisciplinary database recognized for its extensive collection of peer-reviewed literature in the realm of social science research (Bartol et al., 2014; Norris and Oppenheim, 2007). Our search strategy within Scopus was centered around the keyword "social innovation," a pivotal concept within our study's domain. We sought articles published in high-quality journals renowned for their adherence to rigorous research standards. Specifically, we included articles where the term "social innovation" appeared in the title, abstract, or as a keyword.

Initially, our search yielded a vast number of articles, totaling 84,473, reflecting the broad scope of the topic. To narrow down our focus and ensure relevance, we applied filters, with a particular emphasis on the selected journals known for their prominence in the field. To further refine our dataset and uphold standards of quality, we implemented a series of three filters in the initial screening stage. Firstly, we exclusively considered empirical studies, encompassing both quantitative and qualitative methodologies. Secondly, we prioritized studies that clearly disclosed the contextual setting, recognizing the significance of understanding the place-specific dynamics of social innovation. Thirdly, we concentrated on articles specifically addressing social innovation, thereby homing in on content directly pertinent to our research objectives.

Following a structured approach advocated by Baxter, Trott, and Ellwood (2023), we meticulously detailed the selection process for articles that did not meet our specified criteria. Our aim throughout this process was to identify papers that explicitly delved into the context and application of social innovation practices, thereby enriching our understanding of this dynamic field. Furthermore, we employed VOSViewer software to gain insights into the nodes and their connections due to its user-friendly capability in transforming data into a visual tool. VOSViewer employs two standardized weights, namely the number and total strength of the links, to be the nodal network visually. This graphical representation aids in understanding the significance and strength of the links (Donthu, Kumar, and Pattnaik, 2020).

Results. This section presents the findings of our systematic review, focusing on analyzing empirical research within the context of social innovation. Initially, we found 792 articles within the selected journals, but only 197 papers met the criteria for empirical research within a specific context.

The articles were published between 1996 and 2023. Notably, over 60% of this research appeared in the last seven years (2017 to 2023), showing a growing interest in the topic. This trend aligns with the observations made by Lind, Kang, Ljung, and Rosenbaum (2022), who, in their analysis of social innovation literature applied to multinational companies, found a similar surge in interest (Figure 1).

Figure 1 - Number of articles published over the years from 1996 to 2023.

Figure 2 illustrates the central nodes of researchers' countries, generated by VOS viewer with the United States and the United Kingdom occupying central positions. These countries are linked to the results because they are focal points where the context of social innovation articles has been extensively researched and analyzed with a more focused lens. Among the contributors are scholars from Europe (representing the United Kingdom, Netherlands, Spain, Germany, Denmark, Italy, Finland, Belgium, and France), North America (including the United States and Canada), Oceania (with representation from Australia), Latin America only represented by Brazil and Asia (featuring researchers from China, South Korea, India, and Hong Kong).

Figure 2 - Central nodes of researchers' countries.

It is possible to examine the distribution of the research activity in the context of WEIRD within Figure 2, analyzing the country where the research is based. The dominance of the United States and the United Kingdom as the largest nodes aligns with the "WEIRD" characteristics, indicating a concentration of research activity in affluent Western nations with established research infrastructures. Furthermore, the limited participation from countries like Brazil, India, Mexico, and Italy which are typically classified as non-WEIRD or less WEIRD, highlights disparities in research engagement and connectivity. These countries may face challenges in fully participating in the global research community due to factors such as limited resources, access to funding, and research infrastructure. Moreover, non-WEIRD researchers and findings are in a position that they need to engage with WEIRD researchers, while the opposite is not true (Pitesa & Gelfand, 2023).

This analysis underscores the potential bias in social innovation research, where a disproportionate focus on WEIRD countries may skew perspectives and limit the diversity of insights and solutions. Then, from the total of 197 articles, on table 1 it is the breakdown by article per journal, where Journal of Business Research it was the first one, with 72 articles, followed by Research Policy with 53, and Journal of Business Ethics with 28 articles. The Strategic Management Journal had 13 articles, Organization Science, Journal of Business Venturing and Academy of Management Journal had four articles each. And lastly, Entrepreneurship Theory and Practice with three articles. Unfortunately, Administrative Science Quarterly and Business Ethics Quarterly did not have articles that fitted the criteria of choice.

Table 1 - Articles per journal

Journal	Number of Articles
Journal of Business Research	72
Research Policy	53
Journal of Business Ethics	28
Strategic Management Journal	13
Journal of Product Innovation Management	11
Strategic Entrepreneurship Journal	5
Organization Science	4
Academy of Management Journal	4
Journal of Business Venturing	4
Entrepreneurship Theory and Practice	3

As shown in table 1, the Journal of Business Research emerges as a key source. The journal has published 72 relevant empirical articles on the topic of social innovation. The breakdown by region reveals articles analyzing Europe with 28

articles (38.89%), Asia with 20 (27.78%), North America with 7 (9.72%), and 12 in the Group category (16.67%). No articles were found from Latin America (LATAM). Africa and the Middle East contributed 3 and 1 article(s) respectively (4.17% and 1.39%), and Oceania 1 article (1.39%). This distribution could indicate the journal's commitment to diverse perspectives, avoiding an exclusive focus on WEIRD samples. This compromise with diversity can be confirmed with journal website where states "The Journal of Business Research aims to publish research that is rigorous, relevant, and potentially impactful. Recognizing the intricate relationships between the many areas of business activity, JBR examines a wide variety of business decision contexts, processes, and activities, developing insights that are meaningful for theory, practice, and/or society at large."

Table 2 displays the targeted regions and countries in empirical studies. Europe constitutes the primary focus, with 72 articles spanning Spain, Italy, the UK, France, Germany, and others. Asia follows with 41 studies, covering China, India, Vietnam, and more. North America is represented by 35 studies, predominantly concentrated in the United States. The "Group" category comprises 29 studies examining innovation effects across various countries. Africa is explored in 12 studies, while Latin America and the Caribbean feature six studies. Only one study each focuses on Oceania and the Middle East, centered on Australia and Qatar respectively.

North American region is examined, consisting of 35 studies that span the United States, Canada, and Mexico. Notably, within the North American context, there are only nine studies focused on Mexico and seven on Canada, a percentage of approximately 74% of studies only based in the United States setting.

Several common threads appear in the group categories of the articles selected, reflecting a shared focus on the intersection of innovation, business strategies, and societal impact. The studies collectively underscore the increasing significance of human skills, such as creativity and innovation, in the face of digital transformation, emphasizing individuals' pivotal role and capabilities in navigating evolving industries. The exploration of social capital and collaboration on sharing economy platforms further accentuates the importance of human connections in fostering innovation and service advancements. Additionally, the theme of sustainability permeates multiple abstracts, whether it be through examining the integration of corporate social innovations, assessing the sustainability implications of science funding, or finding factors influencing opportunity-driven entrepreneurship that align with sustainable development goals.

Based on the findings across various categories, it is evident that regions characterized as non-WEIRD or less WEIRD include Asia, Africa, Latin America, Oceania, and the Middle East. Focusing solely on studies conducted within these regions, it is apparent that 30.96% of social innovation research is concentrated in these contexts. However, when including studies categorized under the "Group" category, which encompasses multiple regions, this percentage increases to 45.68%, showing a global vision and a comparison between different scenarios.

Table 2 - Categories of countries per quantity of studies

Categories	Countries	Cont
Europe	Belgium, Bulgaria, England, Finland, France, Germany, Hungary, Italy, Netherlands, Norway, Poland, Serbia, Spain, Sweden, Switzerland, Turkey, and the UK.	72
Asia	China, Uzbekistan, India, Vietnam, Taiwan, Hong Kong, South Korea, Nepal, Philippines, Japan, Singapore, Indonesia, Taiwan, Sri Lanka.	41
North America	US, Canada and Mexico	35
Group	Combination of countries	29
Africa	Nigeria, Kenya, South Africa, Tanzania, Sub-Saharan Africa.	12
Latin America	Brazil, Paraguay, Colombia, Chile, Argentina, Nicaragua	6
Oceania	Australia	1
Middle East	Qatar	1

Over the years, there has been a growing interest in diversifying the research scope and the study settings. Currently, studies encompass a broader range of countries, reflecting an expanded global perspective. The articles grouped under this label span from 2013 to 2023, proving a sustained commitment to incorporating diverse contexts and international perspectives in scholarly exploration.

In other words, it is possible to conclude that considering 2005 to 2012, the studies focused on specific locations, such as North America, Germany, Bulgaria. And from 2012 to 2022, it focused on studies with a more complex range of countries, combining different characteristics and specific contexts.

Table 3 - Temporal progression of articles across global regions

	Temporal progression of articles across global regions			
	(1996 - 2002)	(2003 - 2008)	(2009 - 2014)	(2015 - 2023)
Europe	2	6	13	51
Asia	1	1	4	35
North America	2	6	2	25
Group	0	1	5	23
LATAM	0	2	1	3
Africa	0	0	2	10
Middle East	0	0	0	1
Oceania	0	0	0	1

Furthermore, given the significant role of social innovation in addressing both social and environmental challenges, it is pertinent to assess the extent to which academia and literature are dedicated to tackling these issues. The Sustainable Development Goals (SDGs) serve as a comprehensive framework guiding global sustainable development efforts over a 15-year period from 2016 to 2030 (United Nations, 2015). This study provides empirical insights into the prioritization of SDGs within the context of the 2030 Agenda's five fundamental pillars, commonly known as the "5 Ps": People, Planet, Prosperity, Peace, and Partnership. These pillars encapsulate the critical domains necessitating attention to fulfill the agenda's objectives (Barbier and Burgess, 2017).

Out of the 197 articles, the majority fall within the partnership category, encompassing studies that emphasize enhanced global solidarity, tailored to specific needs, and involving the participation of all countries, stakeholders, and individuals, with 74 studies. Followed by prosperity, with 57 studies, with a particular focus on scenarios that can provide people with prosperous and fulfilling lives, generating economic, social, and technological progress occurs in harmony with nature. Then, people with 37 articles, with a particular focus on individual human being and focus on end poverty and hunger, planet with 27, to protect the planet from degradation, including through sustainable consumption and production, sustainably managing its natural resources and taking urgent action on climate change, so that it can support the needs of the present and future generations, and peace with only two articles, to understand on how to foster peaceful, just and inclusive societies which are free from fear and violence, and also understanding more about the politics setting, such as in Zimbabwe and Norway (Table 4).

Table 4 - Classification of articles per SDGs

Classification of articles per SDGs	N•	%
Partnership	74	37.56%
Prosperity	57	28.94%
People	37	18.78%
Planet	27	13.71%
Peace	2	1.02%
Total	197	100%

Analyzing the outcomes of the review and the theories applied to diverse studies on innovation across the years underscores the richness and interconnectedness of the topics, portraying a dynamic research landscape. The array of theories encompasses traditional perspectives such as Schumpeter's and resource-based views (RBV), as well as socio-cultural theories like Social Cognitive Theory, Social Network Theory, and Social Capital Theory. Institutional and behavioral perspectives, delving into aspects like corporate social responsibility (CSR) and stakeholder engagement, have been prevalent.

In recent times, there has been a discernible shift towards contemporary and multidisciplinary theories, reflecting an increased complexity in comprehending and tackling societal challenges. The ascendancy of theories like Dynamic Capabilities, Effectuation, and Social Exchange Theory underscores adaptability, social interactions, and labor relations. The focus on social innovation, circular innovation, and transformative policies signals an enhanced awareness of global challenges. Furthermore, the surge in theories related to entrepreneurship ecosystems, social movements, and co-creation shows a broader and more interconnected approach to innovation.

The integration of theories related to sustainable development, access and benefit sharing, and the framing on the research such as storytelling studies suggests a heightened emphasis on ethical and inclusive innovation. Moreover, attention to the attention-based views of the firm, digital humanism, and mixed methods signifies acknowledgment of the evolving technological landscape and the need for nuanced research methodologies. The exploration of theories addressing hybrid tensions in organizations, social grid approaches, and the societal reminiscence conceptualization shows a deeper understanding of complex organizational dynamics and their societal implications.

In essence, the evolving theoretical landscape reflects an interdisciplinary and globalized approach to understanding and promoting innovation. The transition from traditional perspectives highlights a broader, interconnected view, emphasizing adaptability, sustainability, and social responsibility amid complex and dynamic challenges.

In conclusion, this comprehensive analysis illustrates the global reach and diversity of social innovation research, spanning regions, individual countries, collaborative groups, and continents, contributing to a nuanced understanding of social innovation dynamics worldwide. The analysis of articles reveals that social innovation is becoming less WEIRD over time, with studies adopting diverse country contexts. This diversification enhances knowledge about legitimacy and different regulations globally. Cultural norms can explain why certain beliefs or behaviors are less likely in one country compared to another, but other country-level differences like education, socioeconomic status, and industrialization remain underexplored and offer potential for future research and theorizing (Alley and Cortina, 2023).

Research limitations. While our study offers valuable insights on the social innovation field, such as the evolutionary analysis on the theories utilized in the empirical studies and the analysis of the context of the studies, it is important to acknowledge its limitations. Inherent to our method, particularly in conducting a systematic literature review, are constraints such as the string used for search terms and the selection criteria limited to top-tier and second-tier journals. It is worth noting that variations in search terms could yield different results, potentially broadening the scope of our findings. Other limitations include journal accessibility and the omission of alternative databases that may have returned a different list of articles, but this was overcome using the biggest database, Scopus, with the highest number of journals associated. Despite these limitations, many research areas possess their own distinct journal communities. Thus, focusing solely on top-tier journals could be considered a limitation, as it might overlook less highly rated publications that are nonetheless crucial for the social innovation community. Additionally, this article represents the first exploration of the concept of spatial (geographical) considerations.

Managerial implications. In this article, businesses can benefit from embracing a proactive approach to innovation that encompasses diversity, sustainability, and social responsibility. By leveraging a variety of theoretical frameworks, they can enhance their strategic decision-making processes. Additionally, gaining insights into recent social innovation contexts through research can inform strategic decision-making. This study is also valuable for academia interested in deepening their understanding of the social innovation field.

Originality of the paper. The paper contributes significantly to the discourse on social innovation by comprehensively analyzing empirical studies within the WEIRD (Western, Educated, Industrialized, Rich, and Democratic) context. It addresses the growing interest in social innovation research, particularly concerning its role in addressing societal grand challenges. The paper maps out the locations of social innovation studies by conducting a systematic literature review spanning seven top-ranked journals in innovation, organization, and management. The analysis reveals evolving keyword emphasis over time and a shift towards research in other countries previously overlooked, reflecting changing priorities within the field. Notably, the paper finds that social innovation research is becoming less WEIRD over time, with studies increasingly adopting diverse country contexts, even though the researcher's location is still WEIRD and focused on specific countries such as United States, United Kingdom, France and Spain. The paper contributes by offering an evolutionary analysis of often employed theories, contextualizing research across geographical locations, and understanding the dynamic development of social innovation research.

Furthermore, the paper addresses the tension in scholarly discourse about the positive impact of social innovation and its application by scholars, communities, and governments. By employing the acronym WEIRD, the paper scrutinizes the nature of researchers and the context of their studies. Through a systematic review method, it analyzes 197 empirical research papers and supplies insights into the geographical distribution of social innovation studies. The findings reveal a shift in focus from specific locations to a more complex range of countries, reflecting a broader global perspective. The paper also contributes by offering insights into the theories applied in social innovation research, highlighting a transition from traditional to contemporary and multidisciplinary perspectives. Overall, the paper enhances understanding of social innovation dynamics worldwide and underscores the importance of considering diverse contexts in addressing societal challenges and promoting positive societal outcomes.

Open Innovation search strategies and Innovation performance: differential moderating effects of Big Data Characteristics

GIULIO FERRIGNO¹ SAVERIO BARABUFFI² ENRICO MARCAZZAN³ ANDREA PICCALUGA⁴

Abstract

This extended abstract examines the relationship between open innovation search strategies (breadth and depth) and innovation performance in SMEs. Specifically, it invokes a big data perspective to propose the differential moderating effects of four dimensions of big data characteristics, namely big data volume, variety, velocity, and veracity. Based on a sample of Italian SMEs, our statistical analysis intends to show the positive combinative effects of some big data characteristics and open innovation breadth on radical innovation outcomes and those of other big data characteristics and open innovation depth on incremental innovation outcomes. The findings of differential moderating effects underscore the need to assess the boundary conditions within which OI positively impacts on innovation outcomes. Additionally, they provide valuable insights to managers regarding the significance of big data characteristics in enhancing innovation outcomes through OI strategies.

Key words: open innovation; incremental innovation; SMEs; big data; Italy

Framing of the research. Since Chesbrough's seminal work in 2003, open innovation has increasingly captured the interest of both scholars and practitioners (Bogers et al., 2017; Dahlander et al., 2021), particularly in the domain of R&D management (Ferrigno, Crupi, Di Minin, Ritala, 2023). Open innovation facilitates firms in sourcing external ideas and resources, collaborating on the development of new products and processes with external partners, and leveraging internal ideas that deviate from the firm's current business model (Enkel et al., 2009; Ferrigno, Del Sarto, Cucino, & Piccaluga, 2022; Messeni Petruzzelli et al., 2022: 617), thereby influencing both financial and non-financial performance (Carrasco-Carvajal et al., 2023; Martín-Peña et al., 2023).

A significant focus lies on firms' search strategies within open innovation (Greco et al., 2015; Sà et al., 2023), with established literature supporting the concept of two distinct open innovation search strategies: (1) open innovation breadth, which denotes the number of sources utilized for innovation; and (2) open innovation depth, indicating the level of involvement of these sources in the innovation process (Laursen and Salter, 2006; Messeni Petruzzelli et al., 2022). Both these strategies shape firms' propensity towards acquiring external knowledge (Garriga et al., 2013; Laursen and Salter, 2006) from various sources, including suppliers, customers, competitors, financial institutions, consulting firms, other private enterprises, universities, research centers, and public organizations (Messeni Petruzzelli et al., 2022).

Existing literature has shown that open innovation search strategies affect firms' innovation performance (Cruz-González et al., 2015; Del Sarto et al., 2023; Greco et al., 2016; Henttonen et al., 2011). However, within the contemporary landscape, the proliferation of big data inundates the global sphere incessantly, with its growth trajectory expanding approximately tenfold every quinquennium (Del Vecchio et al., 2018; Hendrickson, 2010; Hilbert & López, 2011). Characterized by datasets of vast proportions that would necessitate significant storage capacities and temporal investments for analysis under conventional systems (Kaisler et al., 2013; Ward & Barker, 2013), big data assumes paramount importance as a pivotal competitive advantage and strategic resource, particularly discernible within the milieu of SMEs (Del Vecchio et al., 2018). In this regard, research has shown that big data may affect open innovation search strategies (Del Vecchio et al., 2018; Ferrigno, Barabuffi, Marcazzan, Piccaluga, 2023). Other scholars found that big data can also bring firms to improve their innovation performance (Ferrigno, Marcazzan, Barabuffi, Piccaluga, 2024; Johnson et al., 2017). Taken together, these streams of literature suggest that big data might play a role in the relationship between open innovation and incremental innovation in SMEs. However, scant research has analyzed whether the relationship between open innovation and incremental innovation is moderated by big data.

Purpose of the paper. *Our paper aims at covering this gap by unveiling what v of the big data can play a moderation effect on the relationship between open innovation and incremental innovation. Big data is a multifaceted concept (Cappa et al., 2021). Thus, this study we refer to the most used characteristics of the big data (also known as 4Vs, see Ghasemaghaei & Calic, 2019): volume (i.e., the amount of data collected); variety (i.e., the assortment of data collected per observation); velocity (i.e., the speed of generating and analyzing data), and veracity (i.e., the reliability and insightfulness of data) (Cappa et al., 2021). Adopting these dimensions, we explore the following research question: what is the moderating effect of the volume, the variety, the velocity, and the veracity of big data on the relationship between SMEs' open innovation and innovation performance?*

To address this research question, we will follow recent studies that have investigated moderating effects around the relationship between open innovation and firm's innovation performance (Cruz-González et al., 2015; Ovuakporie et al., 2021). More specifically, we will firstly hypothesize that the relationship between open innovation search strategies (breadth and depth) and innovation performance (radical and incremental) is positive. After we will assume that some big data characteristics can moderate positively this relationship while others moderate it negatively.

Methodology. *To test our hypotheses, we will gather evidence on the adoption of Big Data from the perspective of SMEs at the individual firm level. To ensure internal validity, we have chosen the Italian context, aiming to control for normative environment, contextual munificence, and entrepreneurial opportunities (Beckman & Burton, 2008). Italy is characterized by a significant prevalence of SMEs, employing over 90% of the national workforce (Cucino et al., 2024; ISTAT, 2022). According to a study by the Italian Ministry of Economic Development (MISE, 2020), Italy demonstrates a notable percentage of firms transitioning towards Industry 4.0. Over the last decade, the Italian Government has initiated numerous plans and interventions to stimulate firms' digitalization and the adoption of Industry 4.0 technologies, including Big Data. Therefore, given Italy's distinctive economic structure primarily based on SMEs and recent national policies aimed at accelerating digitalization, Italy provides an intriguing setting to explore SMEs' behaviors concerning the adoption of Big Data (Martinelli et al., 2021).*

To construct our sample, we will utilize the Italian website "registroimprese" to identify companies involved in developing Big Data technologies. A preliminary search on this website yielded an initial sample of 4357 companies. Since our focus is primarily on analyzing the moderating effects of big data characteristics on the relationship between open innovation search strategies and SMEs' innovation performance, we will narrow down the sample by selecting companies with fewer than 250 employees and a turnover below €50 million (Messeni Petruzzelli et al., 2022). Subsequently, we will employ the Orbis database to access the email addresses and main contacts of these companies. Additionally, we will manually search companies' websites for data that cannot be downloaded. We intend to reach out to the selected Italian SMEs and distribute an online structured questionnaire to be completed by their CEOs or founders. Our objective is to gather more than 150 responses to facilitate a quantitative analysis of the moderating effects of big data characteristics on the relationship between open innovation search strategies and SMEs' innovation performance.

We will test the hypotheses by running several OLS regressions in which the dependent variable is represented by incremental and radical innovation, while the main independent variables are represented by open innovation breadth, open innovation depth and 4Vs of big data. Moreover, the main focus of our analysis is understanding the moderating effect of big data characteristics on open innovation strategies, hence we introduce interaction terms among our main independent variables.

As regards the dependent variables (radical and incremental innovation performance), we will follow the methodologies outlined by Subramanian & Youdt (2005) and Mikalef et al. (2019) and assess radical and incremental innovation using a three-item, 7-point Likert scale through elaborating specific questions that capture these concepts. For the regression analysis, we consider the average score of the multiple responses.

Regarding the operationalization of variables, we will follow the measures used in previous studies on Open innovation search strategies (Messeni Petruzzelli et al., 2022, based on Laursen and Salter, 2006). The explanatory variables of open innovation search strategies (namely (1) open innovation breadth, which denotes the number of sources utilized for innovation; and (2) open innovation depth, indicating the level of involvement of these sources in the innovation process (Laursen and Salter, 2006; Messeni Petruzzelli et al., 2022)) will be computed as it follows. Firstly, we will operationalize open innovation breadth as the count of sources (including suppliers, customers, competitors, financial companies, consulting companies, other private companies, universities, research centers, and other public organizations) collaborating with the SMEs to foster innovative activities. Secondly, open innovation depth will be operationalized as the count of sources with which the firm collaborates "very often" (Messeni Petruzzelli et al., 2022). The variables are computed by summing the number of sources and the number of sources with which a firm collaborates "very often". Consequently, their value ranges between zero (indicating no collaboration, minimum) and eight (maximum), and we will treat Open innovation search strategies as categorical variables.

To gauge the "4Vs" of big data, we draw upon insights from prior research on big data characteristics. Consistent with the approach outlined by Johnson et al. (2017) and Ghasemaghaei & Calic (2020), we evaluate "big data volume," "big data velocity," and "big data variety" using a 7-point Likert scale, ranging from 1 ("strongly disagree") to 7 ("strongly agree"). Conversely, to operationalize "big data veracity," we rely on the work of Ghasemaghaei (2021). The Likert scale allows us to assess the extent of data collected ("big data volume") (Cappa et al., 2021), the diversity of data per observation ("big data variety") (Cappa et al., 2021), the pace of data collection and analysis ("big data velocity") (Ghasemaghaei & Calic, 2020), and the reliability of data collection and analysis ("big data veracity") (Ghasemaghaei, 2021). The measures of "big data volume" and "big data velocity" comprise 4 items each, while those of "big data

variety” and “big data veracity” consist of 3 items. Specifically, for the regression analysis, we consider the average score of the multiple responses.

Furthermore, consistent with previous studies, our model will include the following control variables: (1) whether the SME operates in a high-tech industry or not (Messeni Petruzzelli et al., 2022), (2) the SME's age (Kelly & Amburgey, 1991), (3) the SME's size (Arbore & Ordanini, 2006; Horváth & Szabó, 2019), (4-5) the SME's potential and realized absorptive capacity (i.e., the R&D expenses on total revenue and the number of patents in the last 10 years; see Cassetta et al., 2020; Zahra & George, 2002), and (6) the digital skills of the SME's human resources (measured as the percentage of employees with a STEM degree; see Agostini & Filippini, 2019; Eller et al., 2020; Giotopoulos et al., 2017; Horváth & Szabó, 2019).

Results. In general, we expect that big data characteristics will moderate the relationship between open innovation search strategies and innovation performance. However, taking into consideration the different v of big data (volume, variety, velocity, and veracity) and also the open innovation search strategies (breadth and depth) we also expect that the magnitude of these moderating effects could be different. In particular, we anticipate that some big data characteristics are more important than others in enhancing/downgrading the impact of open innovation breadth/depth on SMEs' incremental/radical innovation.

Research limitations. Although this extended abstract may contribute to our understanding of big data characteristics as moderating variables that affect open innovation search strategies and SMEs' innovation performance, many limitations should be taken into consideration. First, we identified the open innovation search strategies for our study based on the framework established by Messeni Petruzzelli et al. (2021; which is based on Laursen and Salter, 2006). However, we recognize the existence of other open innovation conceptualizations such as those highlighted in different studies that we have not included in our questionnaire. For example, Gassmann et al. (2010) adopt a 'process perspective,' categorizing these practices into inbound, outbound, and coupled OI processes; while Spithoven et al. (2013) suggest four open innovation practices, such as (1) search for external sources of innovation, (2) the acquisition of external R&D, (3) the use of collaborative innovation partners and (4) the exploitation of available IP protection mechanisms. Future research could replicate our methodology while also considering alternative open innovation conceptualizations identified in other studies.

Second, we have scrutinized the relationship between open innovation search strategies and innovation performance and the moderating role of Big Data characteristics within a highly specific setting: Italian (SMEs) listed on the Italian website “registroimprese”. We acknowledge the limited generalizability of our findings to this particular organizational category operating within the confines of this specific national context. Future investigations could explore the moderating effects of big data on open innovation impact on SMEs innovation performance across diverse geographical locations. Moreover, while our study primarily focuses on SMEs, forthcoming research could also examine these relationships on a broader spectrum of enterprises, encompassing established firms, larger corporations, and startups alike.

Third, in this study we analyzed the moderating role played by the most explored v of big data. However, other unexplored dimensions of interest in big data involve variability in data flow, acknowledging the inconsistencies within datasets (Katal et al., 2013), and the realm of big data visualization, which concerns organizations' ability to formulate pertinent inquiries to extract meaningful value from their big data initiatives (Simon, 2014). Future research endeavors could delve into these dimensions of big data to gain a more comprehensive understanding of how they influence open innovation impact on SMEs' innovation performance.

Managerial implications. The expected findings might have implications for managerial practices. More specifically, we emphasize that a more cooperative and collaborative relationship between SMEs and other organizations may facilitate their innovation performance, which is fundamental for those companies that are facing organizational and business challenges that contain their future growth. In general, we expect that open innovation search strategies may allow SMEs to increase their radical and incremental innovation performance. More specifically, we highlight that the magnitude and the path that explain this relationship could be different, depending on the v of big data.

Our research holds potential significance for policymakers as well. Specifically, we aim to demonstrate the importance of policymakers supporting firms in developing tools for analyzing big data. These tools offer valuable insights that facilitate interactions among firms, enabling the exchange of knowledge crucial for enhancing their innovation performance. Therefore, our study underscores the importance of policymakers fostering an environment conducive to the development and utilization of big data analysis tools, ultimately contributing to improved innovation outcomes within firms.

Originality of the paper. The main originality of the paper relies on its focus on the moderating effects of big data characteristics on the relationship between open innovation search strategies and innovation performance. Theoretically speaking, our study could suggest important and peculiar dimensions of big data that may increase or decrease the effect of open innovation search and breadth strategies on SMEs' radical and incremental innovation. Practically speaking, our study can be used not only by SMEs' owner-managers, but also by policymakers in order to promote policies in favor of more cooperative and collaborative behavior in the SMEs' ecosystem by leveraging Big Data.

The role of digital platforms in the university exchange of knowledge: the case of Knowledge Share

MARIAPIA CUTUGNO¹ TINDARA ABBATE² FABRIZIO CESARONI³

Abstract

The concept of digital platforms, from an Open Innovation (OI) perspective, has been a fairly important topic to study in all its characteristics in recent years. This is because OI platforms promote continuous interaction and greater participation between all parties involved, having a significant importance in intermediation between businesses and universities. Open Innovation Digital Platforms (OIDPs) can be considered a specific type of Open Innovation Intermediaries, taking a central role in stimulating, creating and maintaining an ecosystem of successful innovation through continuous interaction and participation between all parties involved. The work intends to investigate the role assumed by an OIDP in the process of exchanging knowledge between the world of research and business, which is increasingly demanding from a technological point of view. We use the case study methodology based on semi-structured interviews. The results underline that the main role of the platform is that of a "bridge" in the process of exchanging knowledge between the world of research (universities, public research centers and private individuals) and companies that move within the environment in which they operate to interface with entities that can design, develop and supply the technology they request. This work records, on the one hand, the limitations of a qualitative analysis based on case studies, on the other, it provides practical and theoretical implications, making an important contribution to the relevant research line.

Key words: *Open Innovation; Open Innovation Intermediary; Open Innovation Digital Platform; Knowledge; Competences.*

Framing of the research. *In recent times, the concept of digital platforms has become increasingly relevance for scholars and managers (De Falco et al., 2017; Hossain and Lassen, 2017). Platforms can be defined as "a set of people, processes, interfaces and artefacts, whose engagement design offers environments of interactions that intensify the actions of agents in creating value" (Ramawamy and Ozcan 2014, p. 34).*

The main focus of past studies has been to investigate how digital platforms, with their advanced web tools and technologies, can open up new ways for organizations to collaborate with external sources to acquire and develop ideas, technologies and knowledge (Hossain and Lassen, 2017). Indeed, digital platforms represent "an important vector for the search for external knowledge" (Hossain and Lassen, 2017, p. 55) and, consequently, for activating new combinations of knowledge and creating new and useful solutions to innovation problems. They enable organizations to bring globally distributed knowledge to solve problems that organizations cannot solve internally on their own (e.g. Jeppesen and Lakhani, 2010).

In digital platforms, the heterogeneity of knowledge stimulates innovation because digital platforms tend to attract complementary innovators (Boudreau, 2010).

Although a significant stream of literature has focused on studying the dynamics of two-sided platforms (Rochet and Tirole, 2003; Economides and Katsamakas, 2006; Hagiu, 2009), OI platforms - a specific type of two-sided platform - (De Falco et al., 2017) represent a less investigated area. In this regard, OI platforms can be understood, essentially, as useful mechanisms for matching solution seekers on the one hand with potential solvers on the other (Eisenmann et al., 2006). This is because OI platforms promote continuous interaction and greater participation between all parties involved. For this reason, OI platforms have "a far-reaching impact on how actors collaborate and innovate together across networks, alliances and business ecosystems. These platforms can be described as virtual environments where heterogeneous entities (e.g. experts, specialized companies, users, R&D laboratories, universities, etc.) are involved in knowledge transfer and integration processes to solve OI challenges (Sawhney et al., 2003; Jeppesen and Lakhani, 2010). This is related to the idea that Open Innovation (OI) approach suggests that companies can respectively use knowledge

inflows to accelerate their internal innovation processes and knowledge outflows to expand their markets, making available knowledge, intellectual property rights (IP) and/or patents to help partners innovate (Chesbrough, 2006).

Given that Open Innovation Intermediaries (OII) use digital platforms to support OI processes, OIDPs can be considered a specific type of OII, taking a central role in stimulating, creating and maintaining a successful innovation ecosystem (Sieg et al., 2010).

An OII is defined as an “organization [...] that provides a supporting role for collaboration between two or more parties during various phases of the innovation process” (Howells, 2006, p. 721), and such organizations have been recognized as being central to implementing and maintaining a successful innovation ecosystem (Sieg et al., 2010; De Silva et al., 2018). In this sense, these organizations are able to act as knowledge repositories, encouraging new combinations of knowledge (Howells, 2006). Although past research has extensively studied the roles and contributions of OIIs and OIDPs, there are no studies investigating the role that these intermediaries assume in the interaction between the world of research and businesses.

OIIs support and are involved in the management and integration of the knowledge base of innovation ecosystems (De Silva et al., 2018). In this context, OIDPs perform tasks ranging from connecting a wide variety of parties for collaboration to building and brokering relationships and bridging a wide range of gaps in knowledge, competences and capabilities (Sieg et al., 2010; Agogue et al., 2013; Mele and Russo-Spena, 2015; Aquilani et al., 2016; De Silva et al., 2018). They can be observed as “an important vector for external knowledge seeking” (Hossain and Lassen 2017, p. 55) and for activating valuable combinations of internal and external knowledge sources with the aim of facilitating the flow of collaboration and sharing knowledge to innovation problems (Aquilani et al. 2016).

Specifically, this type of digital platforms involves the following subjects: platform leaders; actors on different sides of the platform; insert suppliers into the platform leader; and other bodies and institutions that interact with or influence the value and development of a multi-sided platform (Abbate et al., 2021). In this regard, the leader of a platform must design the governance structure, and therefore its own business model of its ecosystem, defining which parties can access and how they can do it, how open the platform is to external suppliers for creating products /services, how the parties can interact, and what the structure of the interactions between the parties on the different sides of the platform is (Abbate et al, 2021; Baglieri et al., 2018).

Purpose of the paper. In recent years the OIDP phenomenon has been increasing, becoming a suitable opportunity to facilitate and support knowledge creation and sharing processes and to improve innovation paths (Abbate et al. 2021). In particular, these platforms can allow organizations to explore suitable external opportunities for new ideas, knowledge and solutions with the involvement and participation of a broad set of external knowledge, decreasing the distance between ecosystem actors. However, despite the rapid accumulation of research contributions on OIDP, as well as the growing relevance of this phenomenon for knowledge sharing and open innovation processes, the number of studies investigating the role of these platforms in the dissemination of knowledge and expertise are still scarce.

For this reason, this work intends to investigate the role assumed by an OIDP in the process of exchanging knowledge and competences between the world of research and the world of business, which is increasingly demanding from a technological point of view.

Methodology. Taking into account the novelty of the phenomenon to be investigated and the inductive nature of the research questions, this study adopts a qualitative method, based on a case study of the digital platform “Knowledge Share” (KS), which allows the exploration of the phenomenon object of this work in its context, using a wide range of data sources (Yin, 2003). This platform was born in the Polytechnic of Turin as a showcase of all the patents developed in the university, to clearly and simply expose all the advantages and the brief description of the technologies covered by the patents. Subsequently, having the need to extend the project to an Italian level, wanting to involve all Italian universities and research centres, KS undertook a close long-lasting collaboration with Netval, creating a network of all the technology transfer offices relating to each associated body. This has allowed us to increase the number of patents included in the platform. Afterwards, for a correct application of patent legislation, and with the need to support inventors in the long patent registration process, KS collaborated and is still collaborating with the Italian Patent and Trademark Office (UIBM).

To carry out the analysis, semi-structured interviews were carried out with KS top management. Information derived from the interviews was triangulated with secondary data, following the recommendation of Eisenhardt (1989). Triangulation of different data sources has been used to mitigate the risk of informant bias, control individuals' subjective judgments, and thus increase construct validity (Gibbert et al., 2008).

Results. Knowledge Share Platform (KS) is a joint project of the Ministry of Business and Made In Italy - Patent and Trademark Office (MIMIT - UIBM), Netval Association and Polytechnic of Turin, which aims to represent for Italian companies the meeting point with the knowledge developed by university research and Research Centers, which can be the subject of concrete application. To date it is the largest national platform dedicated to the valorization of public research. The portal was created with the aim of making information available in a clear and understandable way relating to projects that represent the excellence of the scientific know-how of Italian Universities and Research Centres, in order to resolve the main critical issues linked to the technological transfer and to provide a consolidated tool to channel and simplify interactions between the world of research, businesses and investors. Access is free and open to all large companies, SMEs, investment funds, accelerators and incubators in Italy and abroad and requires registration. By registering on the platform, users will have the opportunity to interact with the project team, access content relating to published projects, send contact requests for technologies and realities of interest to them from which possible collaborations and synergies may arise. The KS 2.0 platform renews the objective of optimizing the contact between

Research and the entrepreneurial fabric but with new and constantly updated user experience and content. In fact, among the great innovations, the patents section has been joined by those of Start-Ups and Spin-Offs: an implementation of great importance especially for the world of current innovation. Not only that, to make it easier for the user to search for projects, KS 2.0 uses AI to improve the "match" between what they are looking for and the projects present on the platform. In addition to further implementations of the platform, the goal of the KS project is to be able to replicate the KS 2.0 platform model internationally through scalable and replicable projects. An arrival point that we are working towards to generate impact through a real ecosystem, in addition to the one that already exists thanks to the KS community in Italy. Knowledge Share has been recognized as best practices by the European Union.

We can say that the KS platform plays a "bridge" role between the world of research and businesses. It is placed in an intermediate position in the process that goes from the birth of innovative ideas by the research world, the subsequent effective application that leads to the birth of a usable technology and the business world which, not having internally the knowledge and competences to develop a certain technology, they look externally (in the platform) for the right technology developed by research centers, spin-offs and start-ups, which they can apply in their own business.

Therefore, KS mainly acts as a "facilitator" of interactions between researchers and entrepreneurs, promoting technology transfer.

Research limitations. This work is affected on the one hand, by the main limitations of a qualitative analysis based on a single case study, on the other hand, it offers ideas both at a theoretical and managerial level for both sides of the platform, the world of research and the world of businesses. The main limitation focused on the analysis of a single case study, therefore, to have a clearer understanding of the role that OIDs have in the field of technological transfer between the world of research and the world of business, it would be useful to analyze other similar platforms to identify points of similarity and points that differentiate them from each other.

Managerial implications. The study highlights that OIDs can effectively help companies that intend to open their organizational boundaries and develop new ideas and solutions with the involvement and participation of external knowledge sources, facilitating and supporting the entire open innovation process.

On the business side, therefore, it is increasingly advisable to open one's horizons by investing in new opportunities emerging from the external environment, increasingly looking for new and innovative technologies that can improve both one's offering to the public and make one's processes more efficient, productive, minimizing their environmental impact, migrating towards a more sustainable vision of doing business by innovating.

On the other hand, from the side of innovation intermediaries, and therefore of OIDs, managers are advised to organize training and knowledge dissemination events much more frequently, at close intervals, which allows companies to come more easily aware of interesting projects that can help them develop useful technologies for their business, thus encouraging an increase in the need to protect their intellectual property with patents or otherwise.

Originality of the paper. The study represents a step forward in the line of research that deals with open innovation through digital platforms, analyzing the role that these platforms can have in the process of technological transfer between the world of research (universities, public research centers and private individuals) and the business world, not having internally the knowledge and competences necessary to develop technologies useful for their business.

The measure of digital maturity

DARIO RUSSO¹ PIERO DEMETRIO FALORSI² FEDERICO CARDONE³

Abstract

Starting from the definition of the concept of “digital maturity”, the research describes its measurement through: a qualitative-quantitative metric which determines the rating of the company to be examined through measurements; a theoretical measurement model applicable to the generality of companies and based on computational algorithms adaptable through parameterization and weighting mechanisms to any reality.

The research focuses on models aimed at identifying an evolutionary path towards the full digital maturity of a company (digital transformation roadmap or “digital transformation”).

Finally, the concrete applications of the approach are described.

Key words: digital maturity assessment, digital transformation

Framing of the research. The models can be distinguished into two types depending on the objective they set and the data they examine: those independent of the economic sector of the company and those specific to a particular economic activity. The former is used for investigations into the digital maturity of a geographical area or an economic sector, and its evolution over time. Consultancy firms use the second type of model to provide companies and administrations with a “snapshot” of their digital maturity and identify the consequent evolutionary path towards full digital maturity (this process is commonly defined as “digital transformation”). Digital transformation requires effective change management, of which measuring results through a well-defined methodology is an indispensable condition.

The paper describes the conceptual model that underlies these approaches, defining the main concepts, highlighting the phases and mechanisms of the measurement process, and finally illustrating the concrete applications. The following definition of “digital” will be adopted below: **The term digital indicates a set of “items” (technologies, organizational solutions and knowledge management systems) that allow the company to exploit information to make operational and decision-making processes more effective and timelier.** The triad of process categories enumerated heretofore, namely technologies (TECH), organizational solutions (ORG), and knowledge management systems (KNOW), when collectively contemplated, assumes paramount significance in shaping the digital orientation of a corporation. This composite amalgamation of TECH, ORG, and KNOW is posited to bestow substantial advantages across diverse dimensions, including but not limited to growth potential, competitive process, focalization on customer/user interests, operational efficiency, adaptability, innovativeness, prognostic acuity, and the augmentation of overall quality. A list of items that can be traced back to the definition of digital is the following:

Category	Digital item	Type
Basic computer systems	Management/operational system	ORG
	Reporting system	ORG
	Internal/external microservices	TECH
Innovative digital technologies	Data platform	TECH
	Robotic process automation	TECH
	Artificial intelligence	TECH
	Machine learning	TECH
	Blockchain/Distributed ledger technology (DTL)	TECH

Rutkowski states: “**Digital maturity** is the ability to quickly respond to or exploit market opportunities based on current technology stacks, people resources and digital technology. A company can undertake digital transformation not only from the point of view of digital technology but on an overall level, including people, culture and processes”. While there is a strong emphasis on technology, a company’s level of digital maturity is also influenced by its speed of response to change and adaptability, mainly due to human capital and automated processes. Finnis defines digital maturity as “an institution’s ability to use, manage, create and understand digital, contextually (suited to its specific environment and needs), holistically (involving vision, leadership, process, culture and organization) and proactive (constantly aligned with the mission of the institution)”. The Boston Consulting Group defined digital maturity as “the measure of a company’s ability to create value through digital”. As a summary of the above discussion, the following definition is proposed in this work: “**Digital maturity measures a company’s ability to seize all the opportunities offered by digital technologies, organizational solutions and skills**”. The research converges on an approach to **digital maturity assessment based on a scale of numerical values** associated with a series of levels, representing a progressive graduation of standard conditions (usually five or six). Each level corresponds to a description of the organization’s situation, examining the presence and use of digital items in its processes. Some examples of models are: the one commissioned by Impulse, a foundation of the German Engineering Association, and conducted by IW Consulting (a subsidiary of the Cologne Economic Research Institute) and the Industrial Management Department of Aachen University; the European initiative Industry 4.0, the model created by the German National Academy of Sciences and Engineering (Acatech); the digital maturity model produced by Google and the Boston Consulting Group; the Deloitte’s Digital Maturity Model, which takes into consideration the five dimensions of the company (customers, strategy, technology, operations, organization-culture), provides a rating on four levels. In summary, the following general definition is proposed: “**A company’s digital maturity is measured according to a Digital Maturity Score (DMS), a multi-level index derived from a series of surveys carried out on all components of the company. The DMS can take values between 0 and L. The numerical scale represents a graduation of digital maturity from low to higher maturity levels**”. In the remainder of the work, the digital maturity measurement scale is proposed, divided into five levels (L=4) reported in following scheme. In the authors’ opinion, the scale represents a good summary of what is proposed in the literature, ensuring a sufficient balance between the need for synthesis and the need for detail that a measurement scale must have.

<i>Digital maturity level Digital Maturity Score (DMS)</i>	<i>Description</i>
<i>0 – Zero</i>	<i>The company needs digital systems to support its operations.</i>
<i>1 – Initial</i>	<i>Business processes are carried out through the partial support of digital applications but still need to be automated.</i>
<i>2- Intermediate</i>	<i>The company began investing in innovative technologies, and some processes were automated. Digital transformation, however, only affects some business areas.</i>
<i>3 – Consolidated</i>	<i>The digitalization plan has been extended to multiple business areas, and the company has automated all core and support processes.</i>
<i>4 – Competitive</i>	<i>The company has integrated automated processes with solutions for data analysis and with a specific governance model. Digital transformation is fully assimilated into corporate culture.</i>

Purpose of the paper. This work aims to build a new theoretical measurement model applicable to the generality of companies and based on computational algorithms adaptable to any reality through parameterization and weighting mechanisms. The paper describes the conceptual model that underlies these approaches, starting from the definitions of the main concepts, highlighting the phases and mechanisms of the measurement process and finally illustrating their concrete application.

The Digital Maturity Measurement DMM of a company is a process aimed at defining the overall numerical value of the company’s DMS. It is based on the comparison between the observations made on the company and what is predicted by the digital maturity model adopted. The maximum value of the DMS represents the existence of all the conditions foreseen by the model. The partial overlap of real situations with what the model predicts for a given level gives rise to DMS values intermediate between 0 and the maximum value L. The DMM process will involve individual parts of the company, and the overall DMS of the company will be a weighted average of the partial DMS.

Methodology. A DMM process is divided into the following steps:

Step 0. Preliminary requirements.

i) Subdivision of the company into elementary parts

In models oriented towards specific economic activities, the choice of classification of the observation areas reflects

the characteristics of the company's organization and directs the data collection activity The classifications can be traced back to a tree diagram which at the first level presents the distinction proposed by Eurostat between core business and support functions: **core business functions** are the activities of a company that produce income, i.e. the production of final goods or services intended for the market or on behalf of third parties; **corporate support functions** are accessory activities carried out by the company in order to allow or facilitate the main corporate functions and its production activity; the outputs of the corporate support functions are not themselves destined directly to the market or to third parties. Starting from this definition, sublevels can be created that gradually descend into more and more detail of the organizational morphology of the company. The table below presents a possible organization of company functions on three levels. That classification allows the value of any variable to be uniquely assigned to a part of the company by identifying it through three subscripts *a*, *b* and *c* (where $a = 1, \dots, A$; $b = 1, \dots, B_a$; $c = 1, \dots, C_{a,b}$) organized in a hierarchical way, where the subscript of a given level depends on the subscripts of the higher level. Thus, concatenating the three subscripts *a*, *b*, and *c* uniquely identifies a firm's elementary part (or leaf). We denote with

$$z_{a,b,c}$$

The value of variable *z* for the part *a*, *b*, *c* of the company.

If one wanted to organize the functions of a company on four hierarchical levels, it would suffice to introduce the subscript *d* where $d = 1, \dots, D_{a,b,c}$. Alternatively, if one wanted to describe the company only on two hierarchical levels, subscripts *a* and *b* would be considered.

First level Subscript <i>a</i>	Second level Subscript <i>b</i>	Third level Subscript <i>c</i>

ii) Choice of digital maturity model

In this fulfilment, we proceed to the textual description of the characteristics that must be undergone for each of the $(L + 1)$ levels provided by the model for each part (trunk, branches and leaves) of the company.

The textual description is made so that if the company is placed at a particular level, say the third, it must also meet all the requirements stipulated in the previous levels.

iii) Choice of the subset of digital items

The third preliminary fulfilment is choosing the subset of digital items and indicating which items should be present in each part of the company for each of the levels of the adopted digital maturity model. This fulfilment is divided into two stages. First, the complete list of digital items that must be considered is established.

Next, we define which technologies from the above list must be used for a specific business part to be characterized by a given level of the DMS. A business function can be classified in a given level of the DMS only if it uses all the items associated with that level.

We denote by j a specific digital item (with $j = 1, \dots, J$) and by ℓ (with $\ell = 0, 1, \dots, L$) a given level of the DMS. We further denote by $t_{a,b,c}(j, \ell)$ a dichotomous variable that takes value 1 if the adopted digital maturity model predicts that the a, b, c part of the firm adopts item j to be characterized by a level ℓ of the DMS, and takes value 0 otherwise. In the example below in Figure below, the value of the variable $t_{a,b,c}(j, \ell)$ for the customer service function ($a = 1, b = 4$ and $c = 3$) is presented.

Digital Item	Index j	DMS Level ℓ				
		0	1	2	3	4
Management/operational system	1	0	1	1	1	1
Reporting system	2	0	1	1	1	1
Internal/external microservices	3	0	1	1	1	1
Data platform	4	0	1	1	1	1
Robotic process automation	5	0	1	1	1	1
Artificial intelligence	6	0	0	1	1	1
Machine learning	7	0	0	1	1	1
Blockchain/Distributed ledger technology (DTL)	8	0	0	0	1	1
Internet of things	9	0	0	0	0	1
Wearable devices	10	0	0	0	0	1
Business analytics	11	0	1	1	1	1
Quantum computing	12	0	0	0	0	1
Cybersecurity	13	0	1	1	1	1
6G Network	14	0	0	0	0	1
Cryptocurrencies	15	0	0	0	1	1
Digital asset	16	0	0	0	0	1
Fintech	17	0	0	0	0	1
Demographic changes	18	0	1	1	1	1
Technologies enabling smart working	19	0	1	1	1	1
Metaverse	20	0	0	0	0	1
Generative AI	21	0	0	0	1	1
Communication plan	22	0	1	1	1	1
Training	23	0	1	1	1	1
Operative model	24	0	1	1	1	1

The matrix shown above is made so that if $t_{a,b,c}(j, \ell) = 1$, we also have $t_{a,b,c}(j, \ell + 1) = 1$.

Step 1. Measurement of the DMS for the elementary parts (leaves) of the company

In this step, we define the value of the DMS, denoted in the following as

$$m_{a,b,c}$$

for each of the elementary parts a, b, c (in which $a = 1, \dots, A$; $b = 1, \dots, B_a$; $c = 1, \dots, C_{a,b}$) into which the company is divided. $m_{a,b,c}$ is an integer taking values from 0 to L . In the digital maturity model, we follow $L = 4$.

Determining the value $m_{a,b,c}$ can be done directly by comparing the company's reality with what is provided in the textual descriptions defined in preliminary fulfilment ii. The direct measurement is then validated by checking whether the set of digital items provided by the theoretical model are all used for the specific business function. Data collection can refer to one of the following four types:

1. interviews;
2. questionnaires;
3. automatic detections by procedures;
4. detections by ad hoc processing.

Direct measurement

Following the most straightforward procedure, the person in charge of the specific business function is asked up to $L + 1$ questions, where the first question in the sequence is the one related to level 0 of the DMS, then moves on to the question corresponding to level $\ell = 1$, and so on. In each question, the surveyor ascertains whether a business function operates according to what is illustrated in the text descriptions related to the level. For example, in the case of the customer service function, the question for level $\ell = 2$ of the DMS is as follows:

The following statement corresponds to the situation in the company? "The business function has begun to invest in innovative technologies, and some of the operational processes have been automated; however, digital transformation does not affect all areas of the function".

In case the answer is positive, the enumerator in charge of DMS assigns value 1 to the dichotomous variable $r_{a,b,c}(\ell)$. It continues with the interview, asking questions corresponding to level $\ell = 2$. In the case that the answer is negative, the enumerator assigns value 0 to the dichotomous variable $r_{a,b,c}(\ell)$ and stops the survey because if a business function does not reach a certain level of digital maturity, it certainly cannot meet the requirements of the next level (see following example).

DMS level ℓ	Question	Value of the variable $r_{a,b,c}(\ell)$
0	Is the customer service function based exclusively on manual processes?	1
1	Are the processes of the customer service function carried out with the partial support of digital applications but are not yet automated?	1
2	The customer service function has begun to invest in innovative technologies and some of the operational processes have been automated; However, doesn't digital transformation affect all areas of the function?	1
3	Has the customer service function automated all operational processes, both core and support?	0
4	The customer service function has integrated automated operational processes with analytics solutions for data analysis and with a specific governance model; Is the digital transformation fully assimilated into the culture of the people who have responsibility for the function?	0

The value $m_{a,b,c}$ is obtained simply by summing the values of the variable $r_{a,b,c}(\ell)$:

$$m_{a,b,c} = \sum_{\ell=0}^L r_{a,b,c}(\ell). \quad (1)$$

Let us now consider a more complicated case in which a specific level of the DMS can only be achieved if two or more requirements are met. In this situation, each condition can be expressed with a single question. The variable $r_{a,b,c}(\ell)$ takes value 1 only if all questions corresponding to the various requirements of the level are answered positively. The measurement of DMS is always done according to formula 1.

Verification of the value of the variable $m_{a,b,c}$ by the digital items

Suppose that the direct measurement has assigned a value of the DMS of the business part (a, b, c) equal to 3, being thus, $m_{a,b,c} = 3$. With respect to preliminary requirement iii, the (a, b, c) function must then adopt all the digital items provided for that level and so it results in $t_{a,b,c}(j, 3) = 1$.

To verify that the $m_{a,b,c}$ level is assigned correctly, it is therefore necessary to conduct a survey to know all the digital items used by the company part in question.

At the end of this survey, the value of a dichotomous variable $u_{a,b,c}(j)$, will be known, where

$$u_{a,b,c}(j) = \begin{cases} 1 & \text{if digital item } j \text{ (} j = 1, \dots, J \text{) is used by the company sector } a, b, c \\ 0, & \text{otherwise} \end{cases}$$

Consequently, from a formal point of view, if the company is assigned level ℓ of the DMS, the following condition must occur

$$\sum_{j=1}^J t_{a,b,c}(j, \ell) u_{a,b,c}(j) = \sum_{j=1}^J t_{a,b,c}(j, \ell). \quad (2)$$

If condition 2 is not verified, the DMM manager has two alternatives. He can lower the level of the variable $m_{a,b,c}$ assigned by direct measurement. Alternatively, he/she can confirm the assessment already given, believing that the detected violation of condition 2 is not so severe as to compromise the company's digital maturity level.

Step 2. Calculation of the DMS for the aggregated parts (branches and trunk) of the holding by aggregating the DMS of the leaves

The calculation of the DMS for the aggregate parts of the firm is obtained by weighted averages of the $m_{a,b,c}$ values determined in step 1.

The digital maturity index for the second-level part b of the company, denoted in the following as $m_{a,b}$, is obtained as

$$m_{a,b} = \text{round} \left(\frac{\sum_{c=1}^{C_{a,b}} \delta_{a,b,c} w_{a,b,c} m_{a,b,c}}{\sum_{c=1}^{C_{a,b}} \delta_{a,b,c} w_{a,b,c}} \right), \quad (3)$$

where: $\text{round}(\cdot)$ denotes the rounding function of the term included in parentheses; $w_{a,b,c}$ is the variable that defines the weight of the part (a, b, c) of the firm; and $\delta_{a,b,c}$ denotes a dichotomous variable that takes value 1 if a part (a, b, c) is present among the parts of the firm and takes value 0 otherwise.

If the maturity index must always be expressed as an integer, rounding defined in step B is required. The transition from natural numbers to integer numbers means that the DMS represents business reality somewhat less accurately. However, it facilitates communication within the company.

It is necessary to use the variable $\delta_{a,b,c}$ because sometimes the subdivision of the company predicted by the theoretical model is not reflected in the company's operational reality. Some elementary parts (a,b,c) may not be recognizable in the operational models adopted by the company.

Similar to the above, the digital maturity index for the function a of the first level is obtained as

$$m_a = \text{round} \left(\frac{\sum_{b=1}^{B_a} \delta_{a,b} w_{a,b} m_{a,b}}{\sum_{b=1}^{B_a} \delta_{a,b} w_{a,b}} \right),$$

where $\delta_{a,b}$ and $w_{a,b}$ have similar meanings to those already illustrated for $\delta_{a,b,c}$ and $w_{a,b,c}$.

Finally, the digital maturity index for the whole company is obtained as:

$$m = \text{round} \left(\frac{\sum_{a=1}^A \delta_a w_a m_a}{\sum_{a=1}^A \delta_a w_a} \right).$$

Choice of weights

The choice of weights is a fundamental process to guarantee the precision of the model, so much so that the weights adopted in the proprietary algorithms of the consultancy companies that certify digital maturity are not made public, for obvious reasons of protection of company secrecy.

The weighting of a model is connected to the following factors:

- the area in which the model is used;
- the state of maturity of the digital technologies considered;
- the strategic orientation of the company which may place greater emphasis on one sector than others

A variety of methods can be used to **determine the weights** $w_{a,b,c}$ at the elementary function level (a,b,c) . Weights can:

1. be defined based on a subjective judgment of the expert responsible for defining the company's digital maturity;
2. assume an equal value for all functions. For example:

$$w_{a,b,c} = 1 / \sum_{a=1}^A \sum_{b=1}^{B_a} C_{a,b};$$

3. be calculated based on a variable that measures the company's commitment to the specific function; such as, for example, the cost associated with resources for carrying out the function;

4. be obtained as a univariate synthesis of different data related to digital maturity available in the company's information systems. This summary can be carried out either subjectively, taking into account the specific company reality, or by adopting a statistical criterion.

- Subjective criterion.
- Statistical criterion. Different statistical techniques can be used for this purpose. In this context, principal

component analysis and factor analysis are the main suggested methods. Synthetic indices are an alternative method that can be used. The weights $w_{a,b}$ and w_a for calculating digital maturity for the company's higher-level functions can be determined either with subjective criteria or as an aggregation of the weights of the elementary functions, or:

$$w_{a,b} = \sum_{c=1}^{C_{a,b}} w_{a,b,c}, w_a = \sum_{b=1}^{B_a} \sum_{c=1}^{C_{a,b}} w_{a,b,c}.$$

Step 3. Presentation of the assessment results

Depending on the model and the measurement scale adopted, the summary result of the assessment is represented by the DMS of the analyzed company, eventually detailed for the different functions analyzed and compared with a benchmark.

Results. The application of the model in the business context enables the achievement of four main objectives:

- 1) drawing a clear vision of business development in terms of digitalization;
- 2) obtaining a competitive advantage through increased revenues and reduced costs resulting from the digitalization process and the introduction of new digital items;
- 3) possibility of comparing oneself with the market and other companies thanks to consistent quantitative metrics;
- 4) possibility of requesting public incentives (e.g. PNRR) thanks to an objective need mapping.

Application procedure

IT tools can apply the model. The use of tools guarantees greater efficiency in the analysis thanks to a highly automated process, and the possibility of immediate comparison of the analyses carried out and the results with the market benchmark, whose indicators are calculated using the same methodology. By applying the theoretical approach presented in this paper, it is possible to calculate the indicators of the company's digital maturity level (DMS), through which an organic digitalization plan (digital transformation) can be designed and implemented.

a. Detection (model steps 0 and 1)

The data collection phase begins with the identification of the level of relevance for the reference sector of each digital item (market appetite) expressed in terms of "Not relevant", "Nice to have", and "Must have" and of the processes in the perimeter for the company's calculation of digital maturity. For each process, the adoption degree of the digital items presents is indicated and expressed in terms of "Low", "Medium", and "High"

b. Processing (model step 2)

The data entered by the company for each process under analysis are automatically processed in order to calculate and subsequently represent:

- Relevance of digital items in the processes, compared to the reference sector;
- DMS of the analyzed company and detail by function (weighted result, calculated vs. relevance of digital items in the industry).

Starting from the data entered as input, relating to the adoption degree of the digital items on the processes, we proceed with the processing. In this phase, the result could be represented through a matrix comprising digital items and processes, which reports the adoption degree.

Presentation of the results (step 3 of the model)

Firstly, the data is processed and combined with the level of relevance or weighting in the reference sector of each digital item. This allows the visualization of the analyzed processes grouped by function according to a graphic matrix. The matrix correlates the adoption degree of the digital items present in the processes and their relevance to the sector. This helps identify the priorities of intervention for the company. For instance, it helps to identify functions whose processes are not very mature compared to the sector they belong to and digital items in which to invest and digitalize. The results are reported using a color scale where red corresponds to low or zero levels of digital maturity. Intermediate digital maturity levels are in orange, and high digital maturity levels are in green. Based on the matrix, it is possible to define a scale of priorities to plan interventions, to bridge the gap between the digital maturity of the company and the reference sector. Functions with lower values (more tending towards red) have a higher priority since there are digital items relevant to the reference sector and with low maturity levels. It is possible to use the resulting matrix to carry out benchmarking, comparing with similar companies or benchmark values. This is thanks to the reprocessing of the input data according to the same methodology. The model comprises three phases that allow us to identify the digital maturity level of the company, its functions, and their priority. This is hypothesized based on the combination of the previous information. Using this data, in the practical application of the model, it is possible and necessary to develop a personalized digitalization plan based on the evidence that has emerged. At this point, expert consultants are expected to intervene, identify priorities, and broaden the analysis with unconsidered business aspects, risk factors, critical business profiles, or compliance needs.

Research limitations. Since this is an approach based on the comparison with an ideal situation described in qualitative terms through assertions that describe the optimal combination between the use of digital technologies and processes, there is a certain amount of discretion which is mitigated through the adaptation of the ideal reference model

to the various company realities and related processes.

Managerial implications. From a managerial point of view, the measurement of the degree of digital maturity of a company and the evidence of the gaps relating to the best performers allow the construction of improvement paths oriented towards specific operational processes and focused on certain technologies. This analysis helps us identify market opportunities, evaluate costs and expected benefits, and estimate macro activation times. The intervention aims to prepare a “Digital Transformation Roadmap”. This is an organic planning of interventions based on prioritization, immediately activating quick win actions, and simultaneously launching structural interventions to increase digital maturity in the medium-long term.

Originality of the paper. Examining the available literature highlights the need for a rigorous conceptualization of the digital maturity measurement process, which in existing approaches adopts algorithms based on empirical evidence drawn from previous assessment experiences. A conceptual description of the digital maturity determination algorithm is contained in Brodny J, Tutak M (2021), where however the focus is placed on the evaluation of the digital maturity of 11 European countries observed as a whole. The article assesses the level of digital readiness of enterprises in these countries based on 14 determinants characterizing the most important areas of the digitalization process. Multi-criteria analysis aimed at assessing the digital maturity of countries was performed using the Multi-Criteria Decision-Making methods (the TOPSIS, MOORA, VIKOR), and entropy methods for delineating the weights of the determinants. To obtain an unambiguous assessment of the determined digital maturity, the mean-rank method was applied. The method of multidimensional scaling allowed for the analysis of similarities between the countries in question.

This work aims to build a new theoretical measurement model applicable to the generality of companies and based on computational algorithms adaptable to any reality through parameterization and weighting mechanisms.

Track 3
International Business

Exploring the impact of cybersecurity on digital export: evidence from food industry

GIOVANNA TERRIZZI* ALBA MARINO•
MARIA CRISTINA CINICI▲ DANIELA BAGLIERI**

Abstract

Although agri-food enterprises have started to use advanced digital technologies for international trade, their exploitation may be hindered by their cyber risk aversion and reluctance to share sensitive information with foreign partners. Accordingly, this study aims to investigate firstly, whether the use of digital technologies has any effect on their export performance and secondly, whether cyber risk aversion may influence digital exporting. Through a quantitative study of a sample of 446 Italian companies operating in the food, beverages and tobacco industry, our results show that digital business technologies are key business assets to sustain export performance and that cyber risk perception negatively moderates digital exports.

Key words: digital technologies; export performance; cyber risk aversion; moderation; food; beverage

Framing of the research. Digital technologies have quickly changed the way international business is conducted (Nambisan, Zahra, & Luo, 2019). They enable firms to access foreign markets through business platforms that facilitate the connection between organizations and enable them to optimize their exchanges (Rakshit, Islam, Mondal & Paul, 2022; Carballo, Rodriguez Chatruc, Salas Santa, & Volpe Martincus, 2022; Marinagi, Trivellas, & Sakas, 2014; Ghalandari, 2013). Their wide availability and accessibility encourage companies of all sizes to leverage them for internationalization and, most often, digital technologies prove necessary for smaller companies that lack resources for more traditional entry modes (Cavusgil & Knight, 2015; Meyer, Li, Brouthers, & Jean, 2023). In recent years, agri-food companies have also started to exploit them to internationalize and efficiently manage trade with their partners, driven by increasingly globalized tastes and lifestyles and the growing demand for authentic food products from traceable and sustainable sources (Carballo, Rodriguez Chatruc, Salas Santa, & Volpe Martincus, 2022; Elia, Giuffrida, Mariani, & Bresciani, 2021; Popkin, 2006; Rashmi, Shree, & Singh, 2017). Moreover, recent Covid-19 pandemic has increased their dependence on digital technologies and online platforms, forcing actors to accelerate their adoption to ensure the continuity of food supplies and respond timely to disruptions (Hew, Wong, Tai, Ooi, & Lin, 2020). Several technologies connect suppliers and buyers through international platforms such as Foodem, Trace Register, Cropin, and Walmart Grocery (Chatterjee, Chaudhuri, Mariani, & Wamba, 2023; Elia, Giuffrida, Mariani, & Bresciani, 2021; McIntyre & Srinivasan, 2017). While Internet of Things (IoT) applications allow to track food in real time along the supply chain and environmental parameters useful for their storage, Blockchain and cloud computing applications allow to share such information with business partners (Ross & Blumenstein, 2015). Extant research shows that these technologies strengthen relationships between distant suppliers and distributors and speed up trade exchange in highly perishable food products, generating transparent, sustainable, and competitive supply networks (e.g., Tsolakis, Niedenzu, Simonetto, Dora and Kumar, 2021; Kittipanya-ngam and Tan, 2019; Crew, 2018). In highly disjointed production contexts, these advanced digital technologies may reduce information asymmetries between firms and enable more efficient business exchanges management without intermediaries and supporting infrastructure (Strange & Zucchella, 2017). Prior literature has recognized the usefulness of such technologies for the internationalization of the agri-food industry on many levels. They facilitate the identification of potential international partners and the connection with them, reduce foreign investment costs and improve the exchange efficiency while minimizing food waste and losses and, consequently, increasing products quality (e.g., Carballo, Rodriguez Chatruc, Salas Santa, & Volpe Martincus, 2022; Rakshit, Islam, Mondal, & Paul, 2022; Hervé, Schmitt, & Baldegger, 2020; Tseng and Johnsen 2011). The integration of digital technologies into agri-

food value chains may also enable companies to seize new opportunities through so-called big data mining, performing market analyses that reveal different purchasing trends in the multiple geographies involved (Wamba, Gunasekaran, Akter, Ren, Dubey, & Childe, 2017; Lee, 2017; Akter, Wamba, Gunasekaran, Dubey, & Childe, 2016). All these advantages of using digital technologies in internationalization strategies may result in export growth and, consequently, better overall economic performance.

Beyond their benefits, these technologies have also raised major cyber security concerns due to numerous hacker breaches against several industry companies since 2017 (Latino & Menegoli, 2022). Among the most serious, ransomware attacks on JBS in 2021, a Brazilian beef producer with factories around the world, and Rovagnati in 2022, an Italian company producing cured meats (Cen, Jiang, Qin, Jiang, Doss, 2023). Accordingly, international activities of agri-food firms through technologies may also be influenced by the perceived cyber risk and the measures put in place to counter it (Guerra & Boys, 2022). GlobalData shows that the percentage of food companies investing in cybersecurity has increased from almost 30% in 2021 to almost 45% in 2022¹. Extant research depicts how companies often adopt various cybersecurity measures to prevent cyber risks (e.g., Hasani, O'Reilly, Dehghantanha, Rezaia, and Levallet, 2023; Latino and Menegoni, 2022). The most common plan of action includes protections against attacks and defense mechanisms for the resilience of affected systems, such as systems vulnerability analysis, staff training on the safe use of digital technologies, antivirus software, firewalls, and data encryption (Zimmermann and Renaud, 2019; Lezzi, Lazoi, and Corallo, 2018). However, current assessments of their usefulness in terms of reducing perceived risk and economic return seem to be insufficient or incomplete. Indeed, previous literature appears to be theoretical and mainly focused on describing the factors that influence the decision to invest in cybersecurity (Hasani, O'Reilly, Dehghantanha, Rezaia, and Levallet, 2023) and measures to protect against particular forms of attack on the food chain (e.g., Manning, 2019, Manning and Soon, 2016), including ideological attacks (Bonell, Meiksin, Mays, Petticrew, & McKee, 2018) and agroterrorism (Spink and Moyer, 2011). Typically, the greater the organizations' risk aversion, the greater the investment in cybersecurity measures (Wessels, van den Brink, Verburgh, Cadet, & van Ruijven, 2021). While many studies consider these preventive actions crucial for corporate security (e.g., Hasani et al., 2023), data reveal they are not sufficient to reduce organizations' risk aversion towards advanced digital technologies. In fact, despite the investments in extensive cyber protection measures, most firms still fear cyber-attacks and feel unprepared to deal with them (World Economic Forum, 2014). Indeed, in highly uncertain contexts, investing in cyber security measures may enhance organizations' awareness of potential risks and, consequently, increase their aversion (van Schaik, Jeske, Onibokun, Coventry, Jansen, & Kusev, 2017). This phenomenon may lead companies to limit the use of the most vulnerable advanced technologies or reduce digital trade with unsafe specific organizations and rogue countries.

Purpose of the paper. Although existing studies have recognized the benefits of using advanced digital technologies, there are still few assessing their effects on food firms' economic performance (Liao, Wang, Baibing, and Weyman-Jones, 2016). Moreover, although studies on cyber risk and cybersecurity actions in the agri-food sector have recently increased, empirical analyses are needed to identify the effects on business performance (Latino and Menegoli, 2022).

Therefore, this project aims to investigate 1) the relationship between advanced digital technologies and export performance and 2) how cyber risk aversion - as the amount of cybersecurity measures taken by organizations - moderates the relationship between digital technologies and export performance. Specifically, in light of above arguments, we formulate the following hypotheses:

Hypothesis 1. The use of advanced digital technologies is positively correlated with agri-food firms' export performance.

Hypothesis 2. Organizations' cyber risk aversion negatively moderates the relationship between digital technology use and export performance.

Methodology. To test our hypotheses, we derive our data from the Survey on Industrial and Services Enterprises (Fonte: Banca d'Italia, Indagine sulle imprese industriali e dei servizi, [2005-2021]), annually conducted by the Bank of Italy. This survey collects information on investments, turnover, and other economic variables of enterprises with administrative headquarters in Italy, operating in the industrial and private non-financial services sectors with at least 20 employees and in the construction sector with at least 10 employees. For this study, we selected a sample of firms operating in the food, beverage, and tobacco industry. Although the focus of our study is not the tobacco industry, it was not possible to further refine the sample selection and limit it to food and beverage enterprises due to the structure of the original data. Moreover, the lack of records for several variables in many years constrained us to limit our analysis only to 2016. As a result, we obtained a cross-sectional dataset of 446 observations. The estimates were made using the Remote Execution (REX) system of the Bank of Italy, which allows remote processing of the data collected in the survey. To safeguard the confidentiality of information specific to the firms participating in the survey, the Bank of Italy limits access to its microdata through a remote processing system, which allows external researchers to perform econometric analyses without having direct access to the microdata.

Table 1 lists the variables relevant to the study. As dependent variable, we considered Export performance corresponding to the logarithm of firm's export sales volume. As independent variable, we considered Digital technology intensity, corresponding to the number of different technologies adopted by each firm, from 0 to 4. As moderator variable, we considered Cybersecurity, that is a proxy of organizations' cyber risk aversion. It is constructed as a factor variable loading two items, namely Cybersecurity investment and Cybersecurity intensity. Cybersecurity investment is a

¹ <https://www.just-food.com/dashboard/jobs/cybersecurity-hiring-levels-in-food-industry-remain-in-growth-data/>

continuous variable that refers to firm's investment in cybersecurity measures, while Cybersecurity intensity is an ordinal variable that counts the number of different cybersecurity measures adopted by each firm, from 0 to 4. Finally, we included five variables to control for firm and environmental heterogeneity.

Since our dependent variable, Export performance, is a continuous measure, we run a linear Ordinary Least Square (OLS) model. Given export performance's potential dependence on its past values, we also incorporate in the model a first-order autoregressive AR(1) process that includes the lagged value of the dependent variable as a regressor (Greene, 2003; Salomon and Jin, 2008; 2010). Its inclusion allows both to account for a dynamic firm-specific component and to control for data serial correlation (Deng, Jean, and Sinkovics, 2018; Reeb, Sakakibara, and Mahmood, 2012; Greene, 2003; García, Avella, and Fernández, 2012). Furthermore, to consider the possible delay with which the use of advanced digital technologies may be reflected in export performance, we specify a regression model with a one step-ahead dependent variable (Wang and Ma, 2018; Gao, Murray, Kotabe and Lu, 2010). In doing so, we mitigate possible endogeneity issues, such as reverse causality between dependent and independent variable, commonly observed in the relationship between international expansion and firm characteristics (Wang and Ma, 2018; Greene, 2003). Therefore, to test our hypotheses, we estimate two dynamic regression models. Firstly, we perform a dynamic regression model to test the positive effect of firm's digital technology intensity on export performance. Then, we perform another dynamic regression model to test the moderating effect of cyber risk aversion on the relationship between firm's digital technology intensity and export performance.

Results. Table 2 shows the descriptive statistics of the variables. For confidentiality reasons, the Bank of Italy does not release the minimum and maximum values of continuous variables. Although digital technologies are increasingly necessary for food, beverage and tobacco enterprises, their adoption appears still very low. Indeed, we note that on average our sample does not use even one of the four digital technologies considered (mean value = 0.38).

Table 3 shows Pearson's correlation coefficients between variables. Correlations between variables are low, excluding potential issues of multicollinearity (Wang and Ma, 2018).

Table 4 shows the results of our regression model. Model 1 represents the baseline model with control variables. As the F statistic is significant, they are collectively relevant in predicting export performance ($F = 87.94$, $p < 0.01$). In Model 2 and 4, we tested our hypotheses. Firstly, we tested the effect of digital technologies on export performance. Accordingly, Model 2 reveals that digital technology intensity has positive effects on export performance ($p < 0.01$). This result supports Hypothesis 1. Secondly, we tested the moderating effect of cybersecurity measures on the relationship between digital technology intensity and export performance. Accordingly, in Model 4, we added the interaction term between digital technology intensity and cybersecurity measures. Our results show that cybersecurity measures negatively moderate the relationship between digital technology intensity and export performance, as evidenced by the negative interaction term ($p < 0.10$). This supports Hypothesis 2, although we do not find strong support for the moderating effect of firm's cybersecurity measures on the relationship between advanced digital technology intensity and export performance.

As regards control variables, Firm size, Firm age, Past export performance and Geographical location - when organizations are located in northern Italy - are positive and significantly correlated with export performance. Surprisingly, product innovation is not significant. According to F statistics, all models in Table 4 have jointly significant coefficients. Whereas R2 indicates that Model 4 fits the data better than other models. Finally, the variance inflation factor (VIF) of each regression model does not exceed 10, indicating no serious multicollinearity problems (Neter, Wasserman, and Kutner, 1990).

To check the robustness of our results, we introduced an alternative measure for digital technologies use, namely Share of investments in digital technologies, which is an ordinal variable ranging from 0 to 4. The results in Table 5 (Model 1 and 2) show a positive but non-significant coefficient. Therefore, Hypothesis 1 is not supported when using an alternative technology use measure; on the contrary, Hypothesis 2 is confirmed.

Research limitations. While acknowledging that the analysis is based on data that may not be considered exceptionally updated, it is essential to note that the nature of the low-tech sector under examination tends to exhibit relatively low dynamics. The unique characteristics of this sector suggest that the impact of digital technologies and cyber risk aversion may have experienced more gradual changes compared to high-tech industries. Consequently, the validity of the results is not necessarily compromised by the temporal gap. Additionally, it is noteworthy that this study stands out as one of the few quantitative investigations exploring the relationship between digital technologies, cyber risk aversion, and export performance in the low-tech sector. Despite the temporal considerations, the scarcity of such empirical research underscores the significance of the present findings, adding a unique dimension to the understanding of how advanced digital technologies impact internationalization strategies in traditionally low-tech industries. Secondly, the study considers small, medium-sized, and large companies alike, but the results may not necessarily be the same between them. Therefore, future studies should verify any differences between different sized enterprises. Thirdly, it is limited to cross-sectional data. The cross-sectional nature of the study provides information on correlations rather than unequivocal cause-and-effect mechanisms. Therefore, a more detailed analysis using panel data would be useful for further research. Finally, through more advanced statistical techniques, future research should consider the potential heterogeneity of the organizations included in the study and the initial differences between groups of companies exposed and not exposed to digital technologies and cybersecurity measures. In the future, the study could also be extended to several countries. Indeed, it is reasonable to assume that digitalization, together with other variables, may have different

effects on internationalization in different economic contexts. The adoption of some forms of digital technologies and cyber security measures are not geographically homogeneous, thus influencing the available policy options.

Managerial implications. The empirical results of this study suggest that food and beverage organizations should consider using advanced digital technologies to improve their export performance. Technology is a key tool to foster international expansion and increase trade efficiency. However, our research shows that high perceived cyber risks could curb their use. Organizations wishing to practice digital exporting should adopt a balanced approach that aims to protect business operations against cyber threats and mitigate perceived risks without compromising the use of technologies to enter and compete in international markets. As a result, they should engage to foster a corporate culture that recognizes both the need to protect data and the importance to innovate for business growth. Targeted training programs, specialized personnel, partnerships with security experts, and modern cybersecurity protocols are critical measures for responsible technology adoption. These measures are twofold; on the one hand, they improve risk awareness and reinforce best practices for addressing them; on the other hand, they bring the company closer to the technology and encourage it to leverage it.

Originality of the paper. This article addresses the call for digital trade studies focused on specific industries. Specifically, we focused on a single industry sector rather than the broader manufacturing environment and advanced technologies rather than the most common technologies, investigating their effect on firms' export performance. On the other hand, our study extends the research on digital exporting by analyzing how certain factors influence this positive relationship and interfere with it. In particular, we study how cyber risk aversion moderates the correlation between technologies and exports. Although the role of technology on internationalization strategies has been the subject of numerous studies, there is no exploration of this phenomenon within a traditionally low-tech sector.

Tables and Figures

Table 1. Variables description

Variables	Type	Description
Dependent variable		
Export performance	Continuous variable	Logarithm of firm's export sales volume
Independent variable		
Digital technology intensity	Ordinal variable	Number of different technologies adopted by each firm, from 0 to 4.
Moderating variable		
Cybersecurity		Factor variable loading two variables, i.e. Cybersecurity Intensity (number of different cybersecurity measures by each firm, from 0 to 4) and Cybersecurity investment (firm's investment in cybersecurity measures)
Control variables		
Firm size	Ordinal variable	Firm size for employees' size classes (1 = 0 - 49 and 2 = 50 and over)
Firm age	Continuous variable	Logarithm of the difference between 2016 and the firm's founding year
Product innovation	Continuous variable	Logarithm of firm's expenditure on trial design and production activities
Geographical location	Ordinal variable	Geographical location of firm (South and islands = 1, Centre = 2, North = 3)
Past export performance	Continuous variable	Logarithm of firm's export sales volume at time t-1.

Industry 4.0, Sustainability, and Internationalization: A Systematic Literature Review

MARTINA TOMASETIG¹

Abstract

In today's rapidly changing business environment, the connection between Industry 4.0, sustainability, and internationalization holds high importance for scholars and practitioners alike. The integration of these three topics has gained significant attention in scholarly discourse in several research fields, from international business (IB) to operations, from sustainability to innovation, marketing, and entrepreneurial studies. This ongoing systematic literature review aims to uncover the relationship between Industry 4.0, sustainability, and internationalization at a firm level. The review employs the PRISMA approach and critically analyzes 55 high-quality journal articles. The research encompasses a descriptive and in-depth thematic analysis to extract insights and provide a thorough understanding of the state of the art. The work delves into the evolving perspectives, conceptual foundations, and empirical studies with the final objective of developing a synthetic framework to help identify the main topics of analysis and propose further research avenues, therefore providing actionable insights and contributing to the evolving discourse on integrating Industry 4.0 with sustainability in an international context.

Key words: Industry 4.0; internationalization; sustainability; literature review; international business; SDGs

Framing of the research. *In today's fast-paced VUCA world, where volatility, uncertainty, complexity, and ambiguity affect organizations' activities (Halloui et al., 2022), the relationship between Industry 4.0, sustainability, and internationalization has emerged as a critical nexus for organizations aiming to thrive in the global marketplace (Ciulli and Kolk, 2023). This research aims to map the existing literature on the convergence of these three topics, which have a transformative potential in understanding how firms do business.*

Digital transformation is moving trillions of dollars in economic value (Rießmann et al., 2015) and has fundamentally altered various aspects of society, including how people live, work, think, and learn (Del Giudice et al., 2021). Digital development influences how firms operate nationally and internationally, boosting flexibility, speed, productivity, and quality (Rießmann et al., 2015) while impacting internationalization processes, competitive advantage, and location choices (Li et al., 2022). Industry 4.0 affects the IB environment, emphasizing the interplay of digital innovation and social engagement, sustainability, and global entrepreneurship (Luo and Zahra, 2023). The impact digitalization has on social, ecological, and economic sustainability - the so-called Triple Bottom Line (Elkington, 1997) - has become a topic of growing interest, leading to flourishing literature that underlines the impact of digital technologies on sustainability at large (Broccardo et al., 2023). The study of the relationship between Industry 4.0 and sustainability is still relatively new. However, it has gained an exponentially growing interest from the academic community, leading to the development of theoretical frameworks (Beier et al., 2020; Isensee et al., 2020; Beltrami et al., 2021; Khan et al., 2021; Touriki et al., 2021; Holzmann and Gregori, 2023) and empirical analyses (Broccardo et al., 2023). Specifically, most recent studies underline the positive effect of adopting digital technologies on sustainable practices (Beltrami et al., 2021) and performance (Broccardo et al., 2023).

Concurrently, human-induced climate change underscores the urgency for sustainable business practices (IPCC, 2023). In this context, the United Nations' Sustainable Development Goals (SDGs) provide a strategic imperative and a global compass for businesses (Del Río Castro et al., 2021; UN DESA, 2023), calling upon the integration of sustainability not only as a societal obligation but also as a crucial component in shaping consumer preferences and business norms (IPCC, 2023). Sustainability efforts move together with the technological development of society (Del Río Castro et al., 2021; Broccardo et al., 2023). Integrating digital technologies and sustainability can drive better efficiency and effectiveness in business operations and reduce environmental impacts (Bag and Pretorius, 2022; Broccardo et al., 2023). Industry 4.0 can enable the implementation of sustainable practices across organizational boundaries, reducing information gaps and promoting collaboration among stakeholders (Ilinitch et al., 1998; Beltrami et al., 2021; Rejeb et al., 2022; Broccardo et al., 2023). Also, sustainability is expected to play a crucial role in pushing organizations toward technology adoption (Beltrami et al., 2021) even though this proposition remains an open question in academia (Rosa et al., 2020; Beltrami et al., 2021; Ghobakhloo et al., 2021; Perera et al., 2023). Sustainability in IB has become crucial

¹ University of Udine
e-mail: tomasetig.martina@spes.uniud.it

for organizations operating in global markets, leading to better environmental performance and management (Gómez-Bolaños et al., 2022).

Ultimately, with the rising between-countries inequalities and polycrisis (UN DESA, 2023), businesses are urged not to abandon global strategies despite global geopolitical tensions (Altman and Bastian, 2023). Internationalization allows firms to develop their activities globally, thus gaining significant competitive advantages in international markets (Jantunen, 2005). In recent years, the discipline has gained substantial interest in the emerging topics of digital technologies (Luo and Zahra, 2023) and sustainable development (Gómez-Bolaños et al., 2022). The degree of firm internationalization has been generally associated with positive, even though not linear, financial performance (Hsu and Boggs, 2003). Nonetheless, scholars have overlooked IB activities' social and environmental effects (Luo and Zahra, 2023).

All these challenges intensify the need for transformative change (Altman and Bastian, 2023), which may be achieved through a better holistic understanding of the complex interrelationships between digitalization, sustainability, and international strategies. The existing literature has partially scrutinized these aspects. However, a significant research gap remains (Ciulli and Kolk, 2023), thus requiring a novel analysis of the matter. Such a need has been underlined in a recent call by the *Journal of International Business Studies* (JIBS), which identifies calls for research to integrate Industry 4.0 and sustainability in IB research (Luo and Zahra, 2023).

Purpose of the paper. This work-in-progress systematic literature review (Massaro et al., 2016) aims to a) identify the main topics arising from studying the relationship between Industry 4.0, sustainability, and internationalization at a firm level in the existing literature and b) point out the directions for future research identified in studies concurrently addressing the three topics.

The study comprehensively reviews 55 high-quality journal articles to achieve its purpose. Through a rigorous examination, we delve into the context of these papers, seeking to extract insights that provide a thorough understanding of the existing state of the research (Paul and Criado, 2020). The review's findings will be synthesized through a dual-analysis approach encompassing a descriptive and in-depth thematic analysis. This approach allows us to uncover the main topics explored in the existing literature. The study's primary objective resides in developing a synthetic framework articulating the primary issues and their interconnection, representing this research domain's state of the art. Finally, the study will extend its impact by proposing future research questions, providing a foundation for developing this field of analysis.

Overall, we aim to respond to a compelling research call, providing a new perspective on the relevance of Industry 4.0 and sustainability in IB research.

Methodology. We employed the PRISMA methodology (Page et al., 2021), a structured approach recognized for its systematic review process. This method encompasses four steps to ensure the review's rigor and replicability – identification, screening, eligibility, and inclusion (Figure 1).

Step 1: Identification. We identified the papers using the Scopus and Web of Science (WOS) databases. Both are deemed two of the most comprehensive databases for academic literature and are widely used for developing literature reviews in various disciplines (Rosa et al., 2020). First, the keyword selection was performed. The keywords are classified into three clusters – Industry 4.0, sustainability, and internationalization. Words referred to Industry 4.0 were identified considering both keywords widely connected to the Industry 4.0 concept (Beltrami et al., 2021), as well as to its technologies at an academic (Frank et al., 2019) and practitioner's level (Rüßmann et al., 2015). The terms related to sustainability considered the work by Beltrami et al. (2021), a literature review on the relationship between digitalization and sustainability, and the work by Sarkis and Zhu (2018), which only reviews papers on sustainability. Finally, the keywords on internationalization were selected considering all the internationalization phenomena. Therefore, the focus was put on broad terms of internationalization (Fan et al., 2021), traditional MNEs (Ocelík et al., 2023), entry modes (Cuervo-Cazurra et al., 2023), and new internationalization phenomena (Paul and Rosado-Serrano, 2019; Romanello and Chiarvesio, 2019). The keywords were combined in a unique string using the OR and AND logical operators. Only articles and reviews in business, management, and accounting areas published in ABS-ranked journals (Chartered Association of Business Schools, 2021) written in English and published from 2011 to 2024 were considered. These restrictions were applied to guarantee the quality of the examined works, thus focusing the analysis on the "best available evidence" (Durach et al., 2017).

Step 2: Screening. The research performed on the Scopus database returned 1.793 results, whereas 1.624 documents were extracted from the WOS Core Collection database. We merged the two into a unique dataset containing 3.417 documents. Next, duplicates were removed, and non-ABS-ranked papers were excluded. The identified sample included 1.485 documents. Microsoft Excel and IBM-SPSS software were used to analyze the results of the research query, identify ABS-ranked papers, and delete duplicates. The documents were thoroughly screened by reading their abstract. Whenever the information provided in the abstract did not discern the paper's content, the full text was screened to assess its coherence with the analysis topic. The complexity of the subject called for an attentive process of exclusion of the papers carried out by the authors. Exclusion criteria were set considering the research aims of the work (Petticrew and Roberts, 2008).

The papers needed to be journal articles or literature reviews. Papers not falling within these categories (e.g., editorials, conference proceedings, book chapters) were removed. Furthermore, the documents needed to address all three topics. All papers missing at least one of these dimensions and works focused only on technical considerations (e.g., engineering studies on specific technologies and optimization simulations not providing managerial contributions) were excluded from the sample.

Step 3: Eligibility Assessment. *Applying the exclusion and inclusion criteria allowed us to identify 55 papers extracted from the two databases. The works were read, analyzed, coded, and classified. In addition to the data extracted from Scopus and WOS, the following information was included for further analysis: type of research (theoretical, empirical, or literature review), the methodology adopted, main research findings and unit of analysis, digitalization topic addressed, sustainability topic addressed, internationalization focus and the interconnection of the three issues, future research avenues suggested, country of study, hypotheses or propositions developed, theoretical lens, framework, model adopted.*

Step 4: Inclusion. *In the final phase of the research, a comprehensive examination of the 55 selected articles was undertaken. This involved a descriptive analysis and an in-depth thematic study, with the final aim of creating a synthetic framework that systematically categorizes studies exploring the nexus of Industry 4.0, sustainability, and internationalization.*

Figure 1: PRISMA 2020 flow diagram for new systematic reviews

Source: our elaboration

Preliminary Results and Future Steps. *Preliminary findings from the analysis, including descriptive and thematic coding, reveal several critical insights regarding the existing literature on the convergence of digitalization, sustainability, and internationalization.*

Descriptive findings. The descriptive analysis followed the fashion of previous literature reviews (Ocelik et al., 2023; Romanello & Chiarvesio, 2019) to achieve a good representation of the research trajectory on the relationship between Industry 4.0, sustainability, and internationalization and to provide a compelling narrative, which underlines the multidisciplinary nature of the topic. The 55 articles were published between 2015 and 2024, with a notable rise in publications culminating in 20 papers published in 2023. The primary source for these articles was the *Journal of Cleaner Production* (9), followed by *Technological Forecasting and Social Change* (5).

Looking at the field categorization provided within the ABS ranking (Chartered Association of Business Schools, 2021), the articles selected belong to several research fields. The works were primarily published in IB and area studies journals (12). However, a great deal of work also comes from outlooks on ethics, CSR, and management (10), sectoral studies (9), innovation (8), and operations management (4). The sample also includes articles published in the fields of information management (2), economics (2), social sciences (2), strategy (1), marketing (1), entrepreneurship (1), organizational studies (1), finance (1) and human resource management (1).

Most of the scrutinized papers were empirical (33). Nonetheless, many theoretical articles are also present in the sample (14), suggesting that a substantial body of work conceptualizes the interrelation of the topics under scrutiny. Finally, 8 papers were literature reviews. The breakdown of empirical papers allows for a further distinction of the methodological characteristics of the studies. Among the 33 papers, 15 employed quantitative methods, 14 qualitative methods, and 4 a mixed method approach.

We can identify two main categories by looking at the geographical distribution of empirical studies. The first includes single-country studies (15). The second refers to cross-country analyses (18). Within the single country set of articles, most are developed within Asia (8) and European countries (4), whereas the African and American continents are scrutinized in 2 and 1 papers, respectively. Most articles opted for a cross-country design, showcasing a global perspective that includes multiple nations and regions. Most empirical papers (8) took an overall international approach.

Thematic analysis. We can glimpse several study perspectives by looking into the content of prior literature reviews. Some reviews address the pressing issues of the impact of COVID-19 on the social sustainability of global supply chains (Sajjad, 2021) or the crisis management potential of digital technologies (Galetsi et al., 2023). Others explore broader trends, such as the transformation of international human resource management and the role of digital technologies in international mobility (Fan et al., 2021) or the potential of Industry 4.0 for sustainable development of GVCs (Awan et al., 2021) and MNEs (Dias Lopes et al., 2023; Ocelik et al., 2023). A growing interest exists in how digital tools can be harnessed for economic growth and social good, especially in developing countries (Ghauri et al., 2022). Concerns around the responsible implementation of digitalization, including cybersecurity risks (Sanili Aydin and Uste, 2022) and ensuring data privacy and ethics (Galetsi et al., 2023), emerge as relevant themes. These reviews provide a valuable foundation for understanding this evolving field, highlighting opportunities and challenges that demand further investigation.

At a conceptual level, the research delves into the intricate connections between digitalization, sustainability, and internationalization (George and Schillebeeckx, 2022). A common theme is the potential of digital technologies, including AI and Big Data, to address sustainability challenges within MNEs and GVCs (Pla-Barber et al., 2021; George and Schillebeeckx, 2022; Wedemeier and Wolf, 2022; Choy et al., 2023; Ciulli and Kolk, 2023; Wang, 2023; Etemad, 2024). These technologies can enhance control mechanisms, improve decision-making, and promote sustainability (Pla-Barber et al., 2021; Choy et al., 2023; Wang, 2023). Nonetheless, concerns exist around the environmental impact of digitalization, such as e-waste, and the potential for exacerbating social inequalities (Dauvergne, 2022; Ciulli and Kolk, 2023; Yi et al., 2023). Interestingly, sustainability is emerging as a driver of internationalization strategies, influenced by changing consumer preferences and pressure to address climate change (Ghauri et al., 2021; Choy et al., 2023; Asakawa and Clegg, 2024; Etemad, 2024). The complex and evolving landscape of IB requires new theoretical frameworks and a focus on the opportunities and challenges digitalization presents (Verbeke and Hutzschenreuter, 2021; Ghauri et al., 2022; Malik and Froese, 2022; Ciulli and Kolk, 2023). Collaboration and partnerships with local stakeholders are crucial for navigating the complexities of IB activities and achieving shared value creation using digital technologies for sustainability (Choy et al., 2023; Yi et al., 2023; Asakawa and Clegg, 2024).

A preliminary review of the empirical studies highlights recurring themes across the literature. Firstly, a distinction can be made between studies addressing MNEs versus international SMEs. Overall, there is widespread recognition of the transformative impact of digital technologies, including Industry 4.0, cloud computing, AI, and 3D printing, in driving sustainability efforts and enhancing organizational competitiveness in MNEs (Tatham et al., 2015; Ajwani-Ramchandani et al., 2021; Il Park and Xiao, 2021; Patchell and Hayter, 2021; Oyinlola et al., 2022; Cortese et al., 2023; Costa et al., 2023; Ferreira et al., 2023; Li, Zhang, et al., 2023). These technologies enable resource optimization, supply chain resilience, and tailored solutions, thereby contributing to environmental conservation, social sustainability, and improved performance and reputation (Stroud, 2020.; Akhtar et al., 2018; Forcadell et al., 2020; Díaz-Chao et al., 2021; Costa et al., 2023; Ferreira et al., 2023; Li, Ye et al., 2023; Li, Zhang, et al., 2023). Conversely, no common understanding of digitalization's positive effects on SMEs' performance is identified. Some researchers argue that digitalization can play a constructive role in SMEs' internationalization and sustainability strategies (Mamabolo and Lekoko, 2021; Del Giudice et al., 2023; Falcke et al., 2023), while other works underscore the challenges deriving from Industry 4.0 and sustainability adoption (De Lucas Ancillo et al., 2022; Dwivedi et al., 2022; Oliva et al., 2022a; Jamwal et al., 2023; Suchek et al., 2023; Choi et al., 2024) and identify those as competing growth paths in case of SMEs' internationalization (Denicolai et al., 2021).

Secondly, several studies delve into business model adaptation and sustainability in IB settings (Asi et al., 2023; Li, Lahy, et al., 2023; Ringvold et al., 2023; Oghazi et al., 2024; Thornton, 2024) underlying the progressive shift of international enterprises' business models towards circular digitally enabled ones. Also, the literature focuses on global supply chain and logistics (Holl and Mariotti, 2022; Marrucci et al., 2022), confirming the positive effect of digitalization on the sustainability of supply chain management.

Finally, research at the individual level addresses consumer attitudes toward digital technologies (Ratten, 2015), providing several insights into the ethical evaluation companies need to consider when introducing digital innovation in global markets.

Future research avenues. Consistent calls for future research permeate the selected works, highlighting the need to address gaps, understand stakeholder interests, and explore implications for governance, organizational structures, and location advantages (Awan et al., 2021; Ocelík et al., 2023).

First, there is a need to analyze the role of Industry 4.0 technologies and circular economy in global supply chains. Existing literature has highlighted the potential of digital technologies in promoting circular economy principles in supply chain management (Awan et al., 2021; Dauvergne, 2022). However, empirical research on the topic is lacking.

Second, novel research shall investigate the role of entry modes and international performance in the context of Industry 4.0. Research has primarily focused on the bright side of digitalization and its effect on sustainable IB (Oliva et al., 2022; Dias Lopes et al., 2023). Nonetheless, a need emerges to delve into the specific entry modes and their impact on IB performance in the era of digitalization.

A third area of novel research addresses the role of digital technologies and environmental costs in global manufacturing. While studies have highlighted the positive impact of digital technologies on environmental and social sustainability in manufacturing (Ferreira et al. 2023; Li, Ye et al. 2023), there is a need to investigate further the potential ecological costs associated with the widespread adoption of Industry 4.0 technologies at an international level.

Finally, Industry 4.0 and sustainable consumption behavior in global markets should be addressed. Existing works have explored the impact of Industry 4.0 on sustainable consumption (Ratten, 2015). However, a gap remains in developing empirical research to understand consumer behavior in the context of digital transformation in diverse international markets.

Future steps for research development. Notably, this research is a work-in-progress. The following research steps will further develop the preliminary findings through a more systematic approach. The next steps will include refining the descriptive and thematic analysis by organizing the data into a synthetic framework. Additionally, conducting a comprehensive literature synthesis to identify critical patterns, themes, and gaps will be crucial. Subsequently, the research can address these gaps through empirical studies that delve deeper into the relationship between digitalization, sustainability, and internationalization. Finally, integrating theoretical perspectives and applying robust methodologies will enhance the credibility and rigor of this literature review.

Research limitations. This ongoing research paper presents limitations that should be acknowledged.

Firstly, the study's scope is limited to a review of journal articles, excluding conference proceedings and book chapters. Given the time required to publish journal articles, this choice may lead to not capturing all the novel research trends.

Secondly, the rigorous analysis approach (Page et al., 2021) may have excluded relevant papers that did not fit the pre-defined inclusion criteria.

Finally, the development of a synthetic framework, while helpful in identifying the main topics of analysis and proposing future research avenues, may not capture the full complexity of the relationship between digitalization, sustainability, and internationalization.

Managerial implications. This work-in-progress research offers valuable insights with significant organizational consequences by reviewing the literature on Industry 4.0, sustainability, and internationalization at a firm level. For researchers interested in pursuing this study area, the preliminary findings highlight some critical research gaps and suggest future research avenues.

For businesses, the research provides valuable guidance on leveraging digitalization to support sustainable practices within IB operations, allowing firms to explore opportunities to enhance resource efficiency, reduce environmental impact, and potentially improve brand reputation. Also, firms can become aware of the downsides of Industry 4.0 adoption and gain an understanding of strategic insights on leveraging digitalization and sustainability for thoughtful international strategies.

Additionally, policymakers can utilize the findings to understand the complex challenges and opportunities at the intersection of digitalization, sustainability, and internationalization. This knowledge can inform the development of policies encouraging MNEs and SMEs to adopt responsible digital business practices in the global marketplace.

Originality of the paper. This ongoing research addresses a critical research gap by conducting a systematic literature review on the convergence of Industry 4.0, sustainability, and internationalization at a firm level.

The work analyzes 55 high-quality journal articles and delves into the context of these papers to extract insights and provide a thorough understanding of the existing state of the research (Massaro et al., 2016). The review employs descriptive and thematic analysis to uncover the main topics explored in the literature, evidencing the primary themes, and offering a representation of the state of the art in this research domain (Ocelík et al., 2023).

The focus on the interplay between these three elements provides a novel perspective on IB research. This work responds to a compelling call for research in the IB area (Luo and Zahra 2023). By highlighting the transformative potential of digital technologies in driving sustainable practices in IB strategies, the research addresses a highly relevant topic in today's rapidly changing business environment. The development of a framework of analysis stemming from the literature review offers a valuable starting point for further discussion and investigation within this emerging field of research.

The advantage of stateness abroad: an analysis of the social networks of state-owned enterprises

GABRIELE GALLI¹ ROBERTO URBANI²

Abstract.

The present research delves into the intricate role of network structures at the board level in steering the internationalization strategies of state-owned enterprises (SOEs). By integrating Social Network Analysis (SNA), this study meticulously explores how network centrality, density, and the diversity of ties influence SOEs' endeavors in global markets. Drawing upon theoretical frameworks from International Business and corporate governance, the analysis scrutinizes the impact of network characteristics on the international activities and market expansion of SOEs, with a particular focus on the European context. The findings reveal that network centrality enhances SOEs' ability to form international deals, while network density is linked to a competitive advantage in global markets. Additionally, the diversity of network ties is found to significantly contribute to successful market expansion. These insights not only shed light on the mechanisms guiding SOEs' global expansion but also underscore the importance of understanding network structures for policymakers, practitioners, and scholars in the field of International Business. The study, while centered on Europe, highlights the broader applicability of its findings to SOEs' internationalization strategies in various geopolitical and economic settings, offering a foundation for future comparative studies.

Key words: *State-owned enterprises, Internationalization, International Business, Foreign markets, Social network analysis, Network theory*

Framing of the research. *State-owned enterprises (SOEs) are becoming increasingly important worldwide. According to the OECD, the proportion of SOEs in the top 500 global companies has seen an increase of three times from the first years of this century (OECD, 2023). SOEs in the OECD area are valued at over 2 trillion USD and are highly concentrated in strategic sectors. Half of SOEs by value operate in the network industries (telecoms, electricity and gas, transportation and postal services) and SOEs cross-border activity has diversified and increased in this century (Cuervo-Cazurra et al., 2014). For decades, SOEs have faced an evolving landscape in different political and geographical areas. During the last century, especially after the Second World War, developed countries have seen a strong increase in the development of new SOEs and in their international activity, while emerging economies led the global scenarios only in the last 30 years (IMF, 2020). This process has led to the creation of global players.*

SOEs contribute to the domestic development and business goals. Moreover, SOEs serve as a vehicle to reach fundamental non-business (political) objectives by governments, such as the supply of critical resources, national security and technological knowledge. A clear example of this phenomenon is the case of the Italian oil&gas national company ENI in Algeria after the beginning of the Ukraine-Russia conflict. With the new agreement, the Italian government was able to solve the incumbent problem of raw materials supply (gas) through the one of main SOEs in the energetic sector.

The International business (IB) literature shows a similar path to the development of SOEs in the business world mentioned before, focusing on different periods, geographical contexts and institutional, political, economic and governance features (Cuervo-Cazurra et al., 2023). For these reasons, SOEs are crucial actors in the international and domestic landscape both, as well as a relevant topic for policy, institutions, firms and practitioners.

This research aims to pose again the attention on the European context as in the seminal papers on SOEs and internationalization, considering the limited attention in the last decade of studies on emerging markets with a prevalence of Chinese companies. In order to reach this goal, we use a social network analysis of European SOEs to investigate the role of network centrality, density and diversity of network ties in shaping their internationalization activity. With this research, we aim to contribute to the ongoing debate on SOEs internationalization extending the view on board of directors features and focusing on a unique international context. Drawing on previous theories and contending their assumptions, we contribute to the literature on SOEs and internationalization, developing a set of hypotheses on SOEs' formal network structure.

Social Network Analysis (SNA) is a methodological approach used to analyze the patterns of interaction among social entities such as individuals, groups, organizations, or even entire societies. This analysis focuses on understanding the relationships and networks that form among these entities and how these relationships impact behaviors, decisions, and outcomes. SNA examines various aspects of these networks, including the structure (like network density or centrality), the quality of relationships (like strength or reciprocity), and the dynamics of network changes over time.

SNA is applied in various fields, including sociology, anthropology, psychology, business, and more recently, in online social media studies. It provides insights into how information flows, how influential certain entities are within a network, and how subgroups and communities form within larger networks.

The book of Wasserman & Faust (1994) is considered a comprehensive and authoritative text in the field, providing both theoretical and practical guidance on conducting social network analysis. It covers a wide range of topics, from basic concepts and measures in network analysis to its applications in various disciplines.

SNA in the field of International Business is a methodological tool focused on analyzing social networks among individuals, groups, organizations, or entire nations. This approach examines how relationships among these actors influence behaviors, resource allocation, information flows, and overall success in the international business context.

SNA emphasizes studying network structures, looking at aspects such as the density of connections, bridges between different groups, or central nodes within the network. This analysis can reveal hidden dynamics, such as power distribution, access to resources, innovation diffusion, strategic alliance formation, and cultural or geographical barriers within and among organizations.

In International Business, SNA is particularly useful for understanding how global networks of communication and cooperation influence business strategies, international expansion, and competitiveness. For instance, it can help companies identify key strategic partners, understand how information travels across different cultures and markets, and develop strategies to navigate complex international networks.

Tichy et al. (1979) is one of the earliest and most influential works applying social network analysis in an organizational context and provides a solid foundation for understanding how this methodology can be applied in the realm of business.

Studying State-Owned Enterprises (SOEs) in the field of International Business is important for several reasons:

a) Economic Impact and Prevalence: SOEs are significant players in the global economy. They often control substantial shares in key sectors such as energy, utilities, and telecommunications. Understanding the operations and strategies of SOEs is crucial due to their impact on global trade and investment patterns.

b) Government Influence and Policy Implications: SOEs are unique in that they are influenced by government policies and objectives. This dual role of being economic and political entities makes it essential to study how they balance commercial objectives with governmental mandates, and how this affects international trade and investment environments.

c) Competitive Dynamics: SOEs can operate under different rules from private sector companies, including receiving state support or subsidies. This can significantly alter competitive dynamics in international markets, raising important questions about market fairness, competition policy, and the level playing field in international trade.

d) Globalization and Market Entry Strategies: SOEs are increasingly engaging in internationalization strategies. Studying their approaches to entering foreign markets, forming international partnerships, and navigating diverse regulatory landscapes contributes to a broader understanding of global business practices.

e) Cross-Cultural Management and Governance: SOEs often have different management and governance structures compared to private firms. This raises interesting questions about how these structures influence international business practices, cross-cultural management, and corporate governance in an international context.

f) Innovation and Technology Transfer: Some SOEs are at the forefront of innovation in their respective industries. Studying them can provide insights into how state involvement affects technological advancement and the international transfer of technology.

g) Response to Global Challenges: SOEs often play critical roles in responding to global challenges such as climate change, energy security, and sustainable development. Understanding their strategies and actions in these areas is crucial for comprehending broader efforts in addressing global issues.

First studies concerning the internationalization of SOEs in IB literature appeared starting from the 1970s, focusing on advanced economies (Aharoni, 1980; Vernon, 1979). Since the beginning of this branch of research, authors suggested different influences and impacts of state ownership on international expansion, highlighting the advantages or disadvantages of states (Cuervo-Cazurra & Li, 2021). However, after these pioneering studies for many years the interest on SOEs vanished, SOEs were considered inherently inefficient entities and in many European countries push forward intensive privatization plans. In the last decade, new studies have emerged especially focusing on emerging economies that led the international environment from early 2000s, reporting state-owned firms' internationalization as a prominent topic in IB literature (Cuervo-Cazurra, 2018; Grøgaard et al. 2019; Cuervo-Cazurra et al. 2023). SOEs are particular kind of companies in which the government (or other national public entities) owns shares of capital, often a majority stake, although minority ownership is sometimes considered within SOEs due to the presence of significant influence in business decisions (Inoue et al., 2013). Moreover, a growing number of studies is considering the new nature of these companies globally, focusing on "hybrid" SOEs, in which the government owns only a partial percentage of equity shares (Estrin et al., 2016; Chen et al., 2018; Bruton et al., 2015).

These types of firms have characteristics related to the specific goals and interests they pursue, thus generating peculiar differences in the ownership and board compared to private firms. Governments can directly influence the

management of such companies to achieve different types of objectives. The first substantial difference from private firms concerns the type of goals pursued, which is not coincident with opportunity to maximise profit. In fact, the State, through its involvement in the capital of companies, wants to ensure the so-called “non-business objectives” that involve the pursuit of national interests (Cuervo-Cazurra et al., 2014), such as the supply of natural resources, energy and security (Bass & Chakrabarty, 2014; Buckley et al., 2008). These non-business objectives may collide with the goal of profit maximisation. Indeed, national interests, driven by politics and governments, are given priority.

Consequently, corporate governance mechanisms in this type of companies present specific characteristics that need more in-depth studies (Grosman et al. 2016), considering, fundamental aspects such as political features, risks and performance (Tihanyi et al., 2019). In international business literature, we can find mixed results about state ownership and internationalization, that confirm the need for more studies. Some authors argue a negative influence of state ownership on firm internationalization (Wu & Chen, 2014; Zhang et al., 2011), while others suggest a positive relationship (Hennart et al., 2017; Benito et al., 2016) or inconsistent results (Liang et al., 2015; Hu & Cui, 2014). However, the influence of state ownership on internationalization remains still unclear (Musacchio & Lazzarini, 2014).

Purpose of the paper. The escalating prominence of state-owned enterprises (SOEs) in the global marketplace, coupled with their evolving roles across strategic sectors, underscores the need for a deeper examination of the factors influencing their internationalization strategies. This paper endeavors to dissect the intricate interplay between network structures at the board level and the internationalization processes of SOEs. Positioned at the nexus of International Business (IB) studies, corporate governance, and social network analysis, the purpose of this paper is multifaceted, aiming to elucidate the underexplored dynamics that shape SOEs' global market activities.

At the core of this investigation is the ambition to unveil how the centrality, density, and diversity of ties within SOEs' board networks impact their internationalization strategies. This focus emerges from a recognition of the profound yet nuanced effects that formal and informal network structures can have on organizational outcomes. Through a detailed social network analysis, this paper seeks to contribute to a nuanced understanding of the network-related mechanisms that facilitate or impede SOEs' international endeavors.

This research is driven by a purpose to bridge critical gaps in the current body of literature concerning the internationalization of SOEs. While previous studies have offered valuable insights into various aspects of SOEs' operations and strategies, there remains a significant lack of understanding regarding the role of network structures. By integrating theories from the realms of IB, corporate governance, and social network analysis, this paper aims to offer a comprehensive framework that can explain the complex dynamics at play in the internationalization of SOEs.

Another pivotal aim of this paper is to recenter the academic discourse on the European context of SOE internationalization. Recognizing the unique political, economic, and institutional landscape of Europe, this study seeks to illuminate how these factors, in conjunction with network structures, influence SOEs' international strategies. This focus is intended to not only fill a geographical gap in the literature but also to provide insights that could inform policy and strategic decision-making within and beyond the European context.

Employing social network analysis as the primary methodological approach, this paper sets out to make a significant methodological contribution to the study of SOEs. By meticulously mapping and analyzing the network structures of SOE boards, this research aims to offer new methodological avenues for exploring the relationship between network characteristics and organizational strategies. This approach underscores the paper's commitment to advancing the methodological tools available for investigating the complexities of SOEs in the international arena.

Beyond its academic contributions, this paper is motivated by the purpose to offer practical implications for policymakers, corporate leaders, and practitioners. By uncovering the roles that network structures play in shaping SOEs' international strategies, this research aims to provide actionable insights that can guide the formulation of policies and strategies to enhance the global competitiveness of SOEs.

In conclusion, this paper seeks to advance our understanding of the internationalization strategies of SOEs by focusing on the role of network structures at the board level, particularly within the European context. Through a comprehensive theoretical and methodological approach, this research aspires to bridge existing gaps in the literature, contribute to the development of new analytical frameworks, and offer practical insights for the effective management and governance of SOEs in the global marketplace.

Methodology. This chapter outlines the methodological framework employed in this study to investigate the influence of network structures at the board level on the internationalization strategies of state-owned enterprises (SOEs). Given the complexity of the research objectives, a multifaceted approach, incorporating Social Network Analysis (SNA) and leveraging a combination of secondary data sources, is adopted. This methodology is designed to ensure a rigorous examination of the network characteristics of SOEs and their correlation with internationalization activities.

The first step involves the identification and selection of European SOEs to be included in the study. The selection criteria are based on the enterprises' state ownership status, their engagement in international activities, and their strategic importance within their respective domestic economies. This process aims to assemble a diverse sample that reflects a wide range of industries and geographical contexts within Europe, ensuring the robustness and generalizability of the study's findings.

The links within the network are defined by the board members' connections across different SOEs. These connections are identified through board membership overlaps, where an individual serves on the boards of multiple SOEs, thereby

creating a link between them. This approach to defining links provides insights into the formal network ties that potentially facilitate information exchange, strategic alliances, and other forms of collaboration among SOEs.

With the firms and links identified, the study proceeds to construct the networks using UCINET, a comprehensive software package designed for the analysis of social network data. The construction of these networks allows for the visualization and analysis of the structural properties of the SOEs' board networks, including centrality, density, and diversity of ties.

Using UCINET, several key SNA metrics are calculated to assess the network characteristics of SOEs. These include:

- *Centrality Measures:* Degree and betweenness centrality are calculated to understand the prominence and influence of individual SOEs within the network.

- *Network Density:* This metric assesses how interconnected the SOEs are within the network, providing insight into the overall cohesion and potential for resource sharing among them.

- *Diversity of Network Ties:* The heterogeneity of the SOEs' connections in terms of industry sectors and geographical locations is analyzed to gauge the breadth of their network exposure.

Data for this study is collected from a combination of sources, including Orbis for corporate information, M&A databases for details on international strategic alliances and other forms of international engagement, and additional industry-specific databases for sectoral analysis. This multi-source approach ensures a comprehensive and accurate dataset for analysis.

The study employs a combination of qualitative and quantitative analytical techniques. For quantitative analysis, regression models are used to examine the relationship between network characteristics and SOEs' internationalization measures, such as the number of international alliances, market expansion, and competitive advantage indicators. Qualitative insights are derived from case studies and thematic analysis of strategic reports and public statements, providing depth to the understanding of how network structures influence SOEs' international strategies.

The methodology outlined in this chapter provides a robust framework for exploring the complex relationships between network structures at the board level and the internationalization strategies of SOEs. By employing a comprehensive approach that combines social network analysis with a rich dataset, this study aims to uncover the nuanced mechanisms through which network characteristics can influence SOEs' behavior and performance in the international arena.

Results. Through the application of Social Network Analysis (SNA), this study has illuminated the intricate ways in which network structures at the board level significantly shape the internationalization strategies of state-owned enterprises (SOEs). The preliminary findings reveal that SOEs occupying central positions within their networks are more adept at forming international alliances, joint ventures, and direct investments. This centrality facilitates access to essential resources and information, thus propelling SOEs towards international engagement. Additionally, the study underscores the competitive advantage gained by SOEs within denser networks, where the interconnectedness among enterprises fosters a conducive environment for knowledge and resource sharing, crucial for navigating international markets. Moreover, SOEs with a broad spectrum of network ties across various industries and geographical regions have demonstrated success in penetrating new international markets, attributed to the diverse insights and opportunities these ties provide.

Research limitations. While this study provides valuable insights into the role of network structures at the board level in influencing the internationalization strategies of state-owned enterprises (SOEs), it is important to acknowledge several limitations that may affect the generalizability and interpretation of the findings. These limitations also highlight areas for further research.

The research primarily concentrates on the European context, examining SOEs within a relatively stable and integrated economic and political landscape. While this focus allows for an in-depth understanding of SOEs' internationalization strategies within developed markets, it may limit the applicability of the findings to SOEs operating in vastly different geopolitical and economic environments, such as emerging or less integrated markets. Future research could address this limitation by conducting comparative studies that include SOEs from diverse geographical contexts, thereby enhancing the global applicability of the findings.

The study's emphasis on Social Network Analysis (SNA) and quantitative metrics for analyzing network structures and their impact on SOEs' internationalization might overlook qualitative aspects that are equally critical. These aspects include the nature of interpersonal relationships within networks, the influence of cultural factors on network dynamics, and the strategic decision-making processes of boards. Qualitative studies, employing interviews, case studies, or ethnographic methods, could provide deeper insights into these dimensions, complementing the quantitative findings and offering a more holistic view of SOEs' network structures.

This research captures a specific snapshot of network structures and internationalization activities, potentially overlooking the evolving nature of these elements over time. Networks are dynamic, with relationships and positions within the network likely to change as SOEs adapt their strategies in response to internal and external factors. Longitudinal studies could address this limitation by tracking changes in network structures over time and their impact on SOEs' internationalization strategies, offering insights into the temporal dynamics of networks and strategic adaptation.

The analysis focuses on formal network ties at the board level, potentially underestimating the role of informal networks, such as personal relationships between executives or interactions at lower organizational levels, which can also significantly influence SOEs' internationalization efforts. Future research could broaden the scope of network

analysis to include both formal and informal network ties, providing a more comprehensive understanding of the networking strategies that facilitate international expansion.

Acknowledging these limitations is crucial for situating the study's contributions within the broader field of international business and corporate governance research. By addressing these limitations in future studies, scholars can build on the findings presented here, further enriching our understanding of the complex interplay between network structures and the internationalization strategies of SOEs.

Managerial implications. The findings from this study on the impact of network structures at the board level on the internationalization strategies of state-owned enterprises (SOEs) carry profound implications for managers and policymakers involved in or with SOEs. These implications are crucial for enhancing the strategic positioning and global competitiveness of SOEs. Herein, we elaborate on the managerial implications drawn from the study's insights.

The study highlights the importance of centrality within SOEs' networks, indicating that SOEs with central positions in their network are more likely to engage successfully in international activities. For managers, this underscores the need to strategically cultivate network ties that enhance the organization's centrality. Building and maintaining relationships with key stakeholders, both within and outside the industry, can provide SOEs with access to vital information, resources, and opportunities critical for international expansion. Managers should, therefore, prioritize networking as a strategic tool, actively seeking board members with extensive connections or investing in relationships that bridge the SOE to new markets.

The positive correlation between network density and competitive advantage in international markets suggests that dense networks, where SOEs are interconnected through multiple ties, facilitate knowledge and resource sharing. Managers should leverage this by fostering a culture of collaboration and information exchange within their networks. Participating in industry consortiums, strategic alliances, and joint ventures can be effective ways to enhance network density. Moreover, policies encouraging inter-firm collaboration can lead to a more cohesive and supportive industry environment, bolstering the international competitiveness of all involved SOEs.

The diversity of network ties, encompassing a wide range of industries and geographic regions, has been shown to significantly contribute to the success of SOEs in international markets. Managers should, therefore, seek to diversify their networks deliberately. This could involve pursuing board members with international experience or forming strategic partnerships with firms in different sectors or countries. Such diversity not only broadens the SOE's perspective and access to different markets but also equips it with varied resources and knowledge bases to navigate the complexities of global expansion.

For policymakers, the study's findings emphasize the role of government in facilitating the internationalization of SOEs through network structures. Policies that encourage cross-border partnerships, international board appointments, and participation in international business consortia can significantly enhance the global reach of SOEs. Governmental support mechanisms, such as facilitating access to international networks through diplomatic channels or trade missions, can also play a crucial role. Furthermore, policymakers should consider the regulatory environment and its impact on SOEs' ability to form and maintain diverse and dense networks.

The managerial implications of this study provide a roadmap for SOEs and their stakeholders to harness the power of network structures for international success. By strategically cultivating centrality, leveraging network density, and exploiting the diversity of network ties, SOEs can significantly enhance their internationalization strategies. Additionally, supportive policies and government actions can amplify these effects, contributing to the global competitiveness and success of SOEs. The insights offered by this study not only contribute to the strategic management literature but also offer practical guidance for managers and policymakers aiming to navigate the complex terrain of international business..

Originality of the paper. The research presented in this paper brings a fresh perspective to the study of state-owned enterprises (SOEs) and their internationalization strategies, contributing original insights to the academic discourse and providing a nuanced understanding of the role of network structures at the board level. The originality of this paper is manifest in several key aspects:

This study breaks new ground by examining the impact of network structures on the internationalization strategies of SOEs, a topic that has received limited attention in existing literature. By focusing on the centrality, density, and diversity of ties within SOEs' board networks, the research sheds light on how these social structures influence SOEs' ability to engage in international markets. This novel focus not only fills a significant gap in the field of international business but also adds to our understanding of the complex dynamics that underpin the global operations of SOEs.

The paper distinguishes itself by centering its analysis on SOEs within the European context, a geographical focus that has been somewhat neglected in favor of studies on emerging markets. This emphasis provides valuable insights into the internationalization processes of SOEs in a developed market environment, highlighting unique challenges and opportunities that arise from Europe's distinct economic, political, and institutional landscape. The European focus enriches the discourse on SOEs by offering a comparative lens through which to view the internationalization strategies of state-owned entities across different global contexts.

Employing Social Network Analysis (SNA) to explore the relationship between network characteristics and the internationalization strategies of SOEs represents a methodological advancement in the field. This approach allows for a detailed examination of the structural properties of networks and their impact on organizational outcomes. By utilizing SNA, the paper introduces a novel methodological framework that enhances the analytical rigor with which the

international activities of SOEs can be studied, offering a model that can be replicated and expanded upon in future research.

Beyond its academic contributions, the originality of this paper also lies in its practical and policy implications. The findings offer actionable insights for managers of SOEs and policymakers, highlighting the strategic importance of cultivating diverse and central network positions to enhance internationalization efforts. By outlining the benefits of dense network structures for knowledge sharing and collaboration, the paper provides a blueprint for SOEs aiming to increase their competitiveness in the global arena. For policymakers, the research underscores the role of network-enhancing policies in facilitating the international expansion of SOEs, suggesting areas for regulatory reform and international cooperation.

Lastly, this paper contributes to ongoing theoretical debates regarding the advantages and challenges of stateness in the context of international business. By integrating insights from corporate governance, international business theory, and social network analysis, the study offers a comprehensive theoretical framework that elucidates the multifaceted influences of state ownership on SOE internationalization. This contribution not only advances theoretical understanding but also invites further scholarly inquiry into the intersecting domains of state ownership, network theory, and international strategy.

In sum, the originality of this paper is evident in its novel focus, geographical emphasis, methodological innovation, practical implications, and theoretical contributions. It paves the way for future research in the field of international business and offers valuable guidance for the strategic management and governance of SOEs in the global marketplace.

La strategia ‘Grab and Go’: Intuizioni teoriche preliminari e possibili implicazioni

MARTINA CASTRONOVO¹ ANNA MINA² PAQUALE MASSIMO PICONE³

Abstract

Sempre più frequentemente, i manager sono chiamati a valutare le strategie di internazionalizzazione da far intraprendere alle loro imprese. Tradizionalmente, le barriere all'ingresso poste in essere dai big player e le distanze esistenti tra mercati domestici e internazionali hanno calmierato l'interesse di espansione geografica. Sebbene queste considerazioni siano ancora valide perché viviamo in un contesto di semi-globalizzazione, le progressive integrazioni tra le economie hanno alimentato l'orientamento delle imprese a valutare con maggiore attenzione le opzioni di espansione. Tuttavia, i potenziali benefici legati all'internazionalizzazione devono essere confrontati con i rischi, le conseguenze e le criticità gestionali di porre in essere investimenti significativi per sostenere l'ingresso in mercati distanti. In questo lavoro - ancora in fieri - noi proponiamo uno schema teorico-interpretativo che consenta di comprendere se e in che modo le alleanze strategiche rappresentano un “cavallo di Troia” e, dunque, supportano la scelta di un'impresa - denominata docking firm - che, tramite l'alleanza stessa, intende penetrare il mercato internazionale. Per avanzare tale argomentazione, questo studio ricorre alla teoria delle opzioni reali. In definitiva, la ricerca concettualizza la strategia grab and go e prova a identificare - almeno concettualmente - una linea di demarcazione tra la cooperazione pura e il camouflage cooperativo.

Parole chiave: alleanze strategiche, coopetition, mercati internazionali, ‘grab and go’, opzioni reali

Inquadramento della ricerca. *Le alleanze strategiche rappresentano un tema fondamentale e frequente, sia nell'ambito della pratica manageriale, sia negli studi di strategia d'impresa, in generale, e di International Business (IB), in particolare. Nel corso del tempo, diversi studi hanno, infatti, esplorato il tema delle alleanze alla luce di diverse e complementari prospettive quali, ad esempio, la Teoria dei Costi di Transazione (Aubert et al., 1996; Hennart, 1988; Kogut, 1988; Williamson, 1989), la Teoria basata sulle Risorse (Andersen & Kheam, 1998, Das & Teng, 2000, 2003; Peng, 2001) e la Teoria Istituzionalista (Dacin, Oliver & Roy, 2007).*

L'interesse allo studio delle alleanze in IB - che si manifesta in un'ampia, continua e copiosa ricerca (Morschett, Schramm-Klein & Swoboda, 2010; Oliveira, Lumineau & Ariño, 2023; Schellenberg, Harker & Jafari, 2018; Zahoor, Khan, & Shenkar, 2023) - muove dalla considerazione che le alleanze costituiscono un'alternativa strategica per le imprese che valutano l'ingresso in nuovi mercati (Brouthers & Hennart, 2007; Dyer et al., 2018), nonché un'importante antecedente alla formazione delle stesse. Un fil rouge lungo tutta la letteratura esistente è che le alleanze consentono alle imprese di avere accesso, ma anche combinare (e ricombinare) risorse e capacità complementari. Se considerate come modalità di ingresso in un mercato internazionale, si suole osservare che le alleanze consentono alle imprese l'accesso a nuovi mercati e il superamento di distanze, siano esse reali e/o percepite, di natura culturale, amministrativa, geografica ed economica (Chen & Hennart, 2002). Allo stesso tempo, tuttavia, le alleanze sottendono delle criticità gestionali e dei rischi connessi, ad esempio, al mancato allineamento culturale e/o strategico tra i partner, che può condurre all'emergere di comportamenti opportunistici (Parkhe, 1993).

Dal momento che «le alleanze non sono molto stabili per natura» (trad. ns, Rajan & Dhir, 2020, p. 352), il numero crescente di imprese che ricorrono alle alleanze - anche tra rivali (Hamel, 1991; Hamel, Doz & Prahalad, 1989; Lado Boyd & Hanlon, 1997; Parkhe, 1993) -, unitamente al crescente numero di alleanze che falliscono ha, di fatto, dischiuso la necessità di indagare sulle ragioni sottese al perché alcune alleanze prosperano, rispetto ad altre che terminano anche prima della loro durata pianificata (Sadowski e Duysters, 2008; Reuer & Zollo, 2005). Se questo è valido per le alleanze, in generale, è ancor più vero per le alleanze in IB (McCutchen. & Swamidass, 2008; Serapio & Cascio, 1996). Ne segue che, parallelamente alla ricerca sui driver sottesi alla formazione delle alleanze, gli studiosi hanno anche indagato gli elementi che ne determinano la dissoluzione.

Se le risorse e le capacità in dotazione dei partner di un'alleanza sono elementi imprescindibili e le complementarità delle risorse spiegano i processi di creazione di valore delle alleanze in mercati internazionali, ma anche la loro eventuale dissoluzione (Dyer et al., 2018), la dissoluzione delle alleanze è dunque da ricondurre alla differenza tra il valore creato dall'alleanza e le aspettative dei partner (Min, 2017). In altre parole, anche nel contesto di IB, la dissoluzione delle alleanze risente delle aspettative dei partner dell'alleanza che ricorrono sin dalla fase di formazione della stessa, definendone, sia le caratteristiche della alleanza, sia il modo in cui i partner sono strategicamente coinvolti nella relazione e, a sua volta, l'evoluzione dell'alleanza stessa. In nuce, riconosciamo che le aspettative sottese alla formazione delle alleanze richiedono ulteriore indagine. Questo lavoro si inserisce in tale dibattito muovendosi dalla letteratura di IB e adottando la prospettiva delle opzioni reali.

Sovente, la decisione di entrare in un mercato estero induce l'impresa a optare tra le tre principali modalità: esportazioni dirette; investimento diretto in un paese straniero (FDI) e; partnership con altre imprese tramite contratti di distribuzione. Diversi lavori hanno adottato la Teoria dei Costi di Transazione ed indagato in che modo l'incertezza ambientale, di settore e di paese, e la specificità delle risorse condizionano le decisioni di ingresso nei mercati internazionali (Anderson & Gatignon, 1986; Gatignon & Anderson, 1988; Gomes-Casseres, 1989; Hennart 1988, 1989, 1991). Altri lavori, emersi a partire dai primi anni del 2000, hanno adottato il modello OLI (Ownership, Location, Internalization) quale quadro teorico e riconosciuto i vantaggi di proprietà e posizione sottese alle scelte di ingresso (Bradley & Gannon, 2000; Brouthers, Brouthers & Werner, 1996; Pinho, 2007; Shrader, Oviatt & McDougall, 2000). Secondo la Teoria delle Risorse, il trasferimento di risorse chiave e complementari consente alle imprese di migliorare il vantaggio competitivo (Barney, 1991). Secondo la teoria Istituzionalista, la formazione di alleanze è rintracciabile nelle disposizioni proprie del contesto istituzionale del paese ospitante (Shellenberg et al., 2018). In estrema sintesi, la letteratura di IB riconosce che, in presenza di incertezza, le imprese preferiscono entrare in nuovi mercati sostenendo livelli inizialmente bassi di investimento che aumentano nel tempo, e la scelta dei tipi di alleanza strategica (licenze, franchising, joint venture, e così via) dipende dalle esigenze dei partner coinvolti e dal contesto in cui operano.

Muovendoci dalla letteratura di IB, in generale, e dal ruolo dell'incertezza per la scelta sulle modalità di ingresso nei mercati internazionali, in specie, (Chi, Li, Trigeorgis & Tsekrekos, 2019; Reuer e Ragozzino, 2014; Trigeorgis & Reuer, 2017; Santoro & McGill, 2005) riteniamo che la teoria delle opzioni reali si presti particolarmente a interpretare il fenomeno. Il ragionamento sulle opzioni reali ci consente di comprendere come le imprese gestiscono le loro alleanze in presenza di asimmetrie informative e di risorse e con conoscenze relativamente limitate sulle dinamiche di mercato in essere (Kogut & Kulatilaka, 2004). Più specificamente, secondo la teoria delle opzioni reali, le alleanze strategiche conferiscono all'impresa entrante una maggiore flessibilità per affrontare elevati livelli di incertezza. Il ragionamento supportato dalla teoria delle opzioni reali mette in luce che se le imprese competono in condizioni di particolare incertezza, possono effettuare piccoli investimenti con la possibilità di consolidarli, espanderli o abbandonarli in seguito. In altre parole, i piccoli investimenti agiscono come un'opzione call che un'impresa può detenere fino alla sua scadenza o esercitare quando si verificano circostanze esterne vantaggiose (Cuypers & Martin, 2007). Le imprese eserciteranno la loro opzione call quando il valore dell'attività sottostante supera il prezzo di esercizio (Cuypers & Martin, 2007).

Obiettivo del paper. *La ricerca - ancora in fieri - accoglie la sfida di concettualizzare una situazione ideal-tipo in cui la conclusione delle alleanze dipende dalla strategia che l'impresa entrante definisce nella fase di formazione. In particolare, il presente lavoro si propone di far leva sul ragionamento alla base delle opzioni reali per tracciare una forma specifica di alleanza strategica in IB. Vedendo le alleanze strategiche come una option call, riconosciamo che l'opzione di partecipare all'alleanza può essere rivalutata e modificata nel tempo. Questo approccio porta a diversi percorsi di azione che l'impresa può seguire nel futuro e concettualizza il camouflage cooperativo che le alleanze possono assumere. Quindi, teorizziamo una strategia "grab-and-go" che informa su un possibile percorso nella fase post-formazione delle alleanze strategiche.*

Seguendo il ragionamento sotteso alle opzioni reali, si interpretano le alleanze strategiche come opzioni call che permettono di differire la scelta di integrazione verticale o orizzontale. Questo passaggio si evidenzia in seno alla definizione dell'accordo, che permette di comprendere se l'alleanza sottende una semplice cooperazione o è una forma di camouflage.

Metodologia. *La ricerca si trova ancora in una fase embrionale di natura teorico-concettuale. Tale fase sostanzialmente speculativa si basa sull'interpretazione -ancora in corso - delle alleanze alla luce della teoria delle opzioni reali. In questo lavoro offriamo una concettualizzazione della strategia grab-and-go quale strategia che consente all'impresa entrante di raccogliere rapidamente risorse e conoscenze necessarie e prendere una decisione informata riguardo l'ingresso in nuovi mercati geografici. Nello specifico, si identificano due fasi: la fase "grab", che muove dalla cooperazione per acquisire le conoscenze e le risorse, l'accesso al mercato e ai fornitori e; la fase "go", dove l'impresa muove dalle conoscenze fino a quel momento acquisite per definire il corso di azione più appropriato. Attraverso la separazione dei due momenti è possibile mettere in luce il passaggio che intercorre tra la fase di "cooperazione visibile" e la fase di competizione. La cooperazione assume la sua "forma visibile" durante la fase grab per poi evolversi verso una forma di interplay di cooperazione e competizione e, dunque, avviare la fase di sostanziale rivalità. Tale forma di cooperazione visibile può assumere la doppia forma di "pure cooperazione" oppure già da subito di camouflage. In quest'ultimo caso emerge direttamente un interplay di cooperazione e competizione dove la competizione è camuffata (filosoficamente, questa forma richiama la matrice Confuciana di cooptation così come concettualizzata da Minà e Dagnino, 2021; Dagnino e Minà, 2021). Di fatti, nella fase go il partner che entra nel mercato rappresenta un potenziale rivale.*

La strategia grab-and-go caratterizza la valutazione delle decisioni di ingresso e delle relazioni con i partner riguardanti le opzioni to defer or stage. In particolare, l'alleanza è vista come una relazione temporanea e altamente indirizzata a rinviare la decisione di integrazione e facilitare un processo di ingresso graduale per superare le barriere d'ingresso e impedire reazioni dei rivali già presenti nel mercato.

La concettualizzazione proposta può essere d'uopo per approfondire le seguenti fasi. La prima fase è quella di Grab. Questa è la fase di coinvolgimento in cui l'impresa entrante (denominata docking firm) inizia una relazione apparentemente cooperativa con una impresa (denominata docked firm) nel mercato di destinazione. Questa cooperazione funge da opzione call e consente alla docking firm di acquisire le conoscenze e le risorse necessarie per valutare le varie incertezze legate alla penetrazione in un nuovo mercato. L'obiettivo è raccogliere informazioni sul mercato target (dinamiche competitive, preferenze dei clienti, fattori regolatori e altre informazioni rilevanti). Sfruttando la relazione con la docked firm, l'impresa entrante ottiene accesso alle conoscenze e alla rete del partner. Ciò renderà, ad esempio, più facile una rapida ed efficiente raccolta di informazioni sul nuovo mercato. Questa fase è caratterizzata dal trasferimento di conoscenze, dalle attività congiunte e dalla collaborazione per costruire una solida comprensione del mercato estero. In questa fase, l'impresa assume un comportamento di cooperazione visibile dove la rivalità rimane potenziale, e la sua evoluzione dipende dai cambiamenti e dagli sviluppi nel mercato.

La seconda fase è la fase Go: se sono stati registrati effetti positivi durante la fase di grab, l'impresa può decidere di esercitare l'opzione in modo espansivo, dando origine a processi di integrazione verticale (configurandosi come option to alter scale) o di integrazione orizzontale (configurandosi come option to grow). Al contrario, se le variazioni registrate non sono allineate alle aspettative e stanno diminuendo, l'impresa può scegliere di non esercitare l'opzione (se la relazione cooperativa non ha iniziato ad assumere una prospettiva cooperativa) o piuttosto esercitare l'opzione di uscita, terminando la relazione.

Implicazioni pratiche. *La principale implicazione del nostro studio riguarda la selezione del partner. L'alleanza rappresenta uno strumento per prendere decisioni non estremamente vincolanti per il futuro, consentendo all'impresa entrante di esercitare l'opzione in seguito. Chiamando l'attenzione sul rischio di una strategia grab-and-go, riconosciamo l'importanza dei segnali lungo l'alleanza. Se la docked firm riuscisse a cogliere le vere intenzioni prima che la docking firm possa esercitare l'opzione, potrebbe mettere in atto una serie di azioni che anticipino la durata della fase go, riducendo le probabilità di esercitare l'opzione. Tuttavia, noi riconosciamo la complessità di identificare i segnali trasmessi in modo indiretto dall'impresa docking e determinare la scadenza anticipata dell'opzione con conseguente effetto rebound.*

Originalità del paper. *La ricerca, ancora in corso, mira ad offrire la concettualizzazione della strategia grab-and-go alla luce della prospettiva teorica delle opzioni reali e, successivamente, proporre delle analisi empiriche (di tipo qualitativo-longitudinale). La ricerca affronta gli argomenti proposti da Min (2017) secondo cui la fine delle alleanze può essere attribuita alla differenza tra il valore creato da un'alleanza stessa e le aspettative dei partner. Concettualizziamo questa strategia in due fasi. Nella fase di grab, l'impresa focale decide di strutturare la cooperazione per acquisire conoscenze sul nuovo mercato geografico e le risorse necessarie per competere in tale mercato. Nella seconda fase - la fase go - l'impresa può decidere di entrare nel mercato attraverso flussi di integrazione verticale o orizzontale diretta, proporre un'operazione di business combination o uscire. In questo modo, contribuiamo alla letteratura esistente in due modi. In primo luogo, concettualizziamo il camouflage cooperativo che l'alleanza strategica può assumere. Sosteniamo che il momento della selezione del partner sia cruciale per attivare il processo e parlare della strategia grab and go. L'idea è che le imprese cercano di allearsi sfruttando una tattica di camuffamento, ovvero di aprire un'opzione strategica. Quindi, studi successivi alla luce della teoria delle opzioni reali potranno consentirci di identificare taluni criteri di partner selection che si rivelano cruciali per avviare tale processo strategico. Questa riflessione ha anche implicazioni per la struttura dell'alleanza. In particolare, nonostante non richieda investimenti significativi, le docking firm saranno inclini a strutturare un'alleanza strategica attraente per le docked firm. Questo tipo di alleanza non segue criteri altamente definiti, ma è la migliore forma che consente di avvicinarsi al partner rispetto agli obiettivi finali di ingresso e soprattutto di camuffamento. Questa ricerca potrà contribuire a identificare il ciclo di vita delle alleanze strategiche in cui la cooperazione iniziale è solo una fase transitoria o, di fatto, uno step di camuffamento. Da un punto di vista teorico questo significa rappresentare le alleanze strategiche come trampolino di lancio per la competizione in tempi successivi.*

L'imprenditorialità femminile migrante nei business familiari

GIULIO PALMAS¹ MICHELA FLORIS²

Abstract

L'imprenditorialità femminile migrante costituisce un'area di studio dinamica e in costante evoluzione, distinguendosi per le sue peculiarità legate a contesti personali, strutturali e socioculturali. Gli studi evidenziano che questo tipo di imprenditoria è profondamente radicata in una struttura sociale e culturale, sostenuta da reti familiari ed etniche essenziali per l'avviamento e la gestione dell'attività. Nonostante l'aumento dell'interesse accademico, l'imprenditoria femminile migrante, in particolare nelle aziende familiari, rimane un'area ancora parzialmente esplorata. Utilizzando la lente teorica dell'embeddedness multipla, questo studio intende esplorare le complesse dinamiche che caratterizzano le imprese gestite da donne migranti, con un focus specifico sulle interazioni tra i fattori contestuali, familiari e individuali che contribuiscono al successo. Attraverso l'analisi approfondita delle esperienze di dieci imprenditrici migranti, il presente studio mira a delineare i fattori che sostengono o ostacolano i percorsi imprenditoriali, mettendo in luce l'importanza del contesto socio-economico e culturale, nonché delle reti di supporto familiare ed etnico, e del capitale umano individuale. L'aspetto innovativo di questa ricerca consiste nello studio dell'interconnessione tra questi elementi, evidenziando come la resilienza individuale e il sostegno etnico-familiare hanno facilitato l'adattamento a contesti imprenditoriali ostili. I risultati di questo studio mettono in luce una varietà di esperienze eterogenee, enfatizzando l'urgenza di adottare approcci più integrati e personalizzati nei programmi di supporto alle imprenditrici migranti. Questo studio non solo contribuisce al dibattito sull'imprenditorialità migrante ma fornisce spunti importanti per responsabili politici e attori del supporto imprenditoriale, sottolineando la necessità di migliorare l'accesso a risorse, formazione e reti di supporto. Infine, si evidenzia la necessità di ulteriori studi per esplorare la varietà di percorsi imprenditoriali migranti, al fine di promuovere un ecosistema più inclusivo e sostenibile.

Key words: *imprenditorialità femminile migrante; reti familiari ed etniche; aziende familiari; Embeddedness multipla; dinamiche imprenditoriali; sostenibilità aziendale*

Framing of the research. *L'importanza di esaminare l'imprenditorialità femminile migrante risiede nella sua correlazione con gli obiettivi fondamentali dell'Agenda 2030 delle Nazioni Unite per lo sviluppo sostenibile. In particolare, questa ricerca si allinea con l'obiettivo 5, che mira a "Raggiungere l'uguaglianza di genere ed emancipare tutte le donne e le ragazze", contribuendo all'emancipazione femminile attraverso la creazione di opportunità economiche e promuovendo l'uguaglianza di genere nel mondo dell'imprenditoria. L'obiettivo 8, volto a "Promuovere una crescita economica sostenuta, inclusiva e sostenibile, occupazione piena e produttiva e un lavoro dignitoso per tutti", viene supportato incoraggiando una crescita economica inclusiva attraverso l'innovazione e la creazione di posti di lavoro offerti dalle imprese guidate da donne migranti. Infine, con l'obiettivo 10, che si propone di "Ridurre le disuguaglianze sia all'interno dei Paesi che tra di loro", la ricerca promuove l'integrazione sociale e la riduzione delle disuguaglianze economiche e sociali, evidenziando il contributo significativo delle donne migranti all'economia e alla società dei paesi ospitanti e di origine. (Nazioni Unite, 2023).*

Le iniziative imprenditoriali da parte delle donne migranti non solo garantisce il sostentamento proprio e delle famiglie ma contribuisce anche allo sviluppo economico e sociale sia delle comunità ospitanti sia di quelle d'origine. (Chreim, Samia, et al. 2018)

Inoltre, la necessità di approfondire questi argomenti è accentuata dal contesto globale caratterizzato da veloci mutamenti geopolitici, economici e sociali. I recenti conflitti in Ucraina e Palestina, uniti alle ripercussioni della pandemia di Covid-19, hanno influenzato non solo i flussi migratori ma anche creato nuove opportunità e sfide per le imprenditrici migranti. In particolare, la crisi migratoria a seguito dell'invasione russa dell'Ucraina nel febbraio 2022 ha creato un ingente flusso migratorio verso l'Europa, mettendo sotto pressione le politiche di asilo e migrazione degli Stati membri dell'UE. Secondo le ultime stime al febbraio 2024 fornite da UNHCR, più di 6 milioni di profughi ucraini si trovano attualmente in Europa, con un notevole numero di essi che ha cercato asilo in paesi confinanti come Polonia,

² Università di Cagliari
e-mail: michela.floris78@unica.it

Repubblica Ceca, Bulgaria, e Romania, oltre che in destinazioni più lontane come Germania e Regno Unito. (UNHCR, 15 febbraio 2024)

In risposta all'ingente afflusso di rifugiati verso l'Europa, l'Unione Europea ha attivato il meccanismo di protezione temporanea. Questa misura straordinaria, introdotta per la prima volta con la Direttiva 2001/55/CE, mira a offrire un rifugio sicuro e un accesso rapido ai diritti fondamentali per coloro che fuggono da situazioni di emergenza. Questo strumento risulta particolarmente rilevante per le imprenditrici migranti, poiché questa protezione temporanea fornisce accesso immediato al mercato del lavoro, alloggio, istruzione per i loro figli, assistenza medica e sociale, creando così una base da cui possono avviare o continuare le proprie attività imprenditoriali.

La pandemia di Covid-19 ha imposto sfide senza precedenti, in particolare la chiusura delle frontiere ha colpito duramente le imprese gestite dai migranti, specialmente quelle dipendenti dal commercio transfrontaliero. Questo contesto ha accentuato le sfide già esistenti nel settore formale a causa di barriere socio-culturali, economiche e politiche, spingendo molti migranti ad operare in lavori informali. Le donne, in particolare, si impegnano in una serie di attività nel settore informale, a causa della possibilità di operare senza il bisogno di capitali ingenti o competenze specialistiche, utilizzando queste occupazioni come ultima risorsa per sopravvivere nell'ambiente urbano dinamico. (Jenberu, Kasse, 2021) Questo contesto ha reso alcune donne completamente dipendenti dai loro partner o dalle reti di supporto per la sopravvivenza, limitando la loro autonomia finanziaria e aumentando la loro vulnerabilità economica. Sebbene alcune donne abbiano ricevuto aiuti da ONG, chiese e reti sociali, l'accesso a tali supporti variava significativamente in base allo status di rifugiato, alla classe sociale e ad altri fattori intersezionali. Le donne con uno status legale meno stabile, come le richiedenti asilo, avevano meno probabilità di accedere agli aiuti governativi. Nonostante queste sfide, è emersa una forte solidarietà all'interno delle comunità di migranti, con esempi di condivisione di risorse limitate e supporto reciproco. (Mulu, 2021)

Gli sviluppi tecnologici, compreso l'uso dell'automazione, dell'intelligenza artificiale e della robotica, stanno trasformando i mercati globali, offrendo sia nuove opportunità che sfide significative, in particolare nei settori a bassa qualificazione dove i lavoratori migranti sono spesso impiegati. Inoltre, la disparità digitale, dovuta a limitazioni nell'accesso a internet, rappresenta un ostacolo significativo. Sebbene le nuove tecnologie creino nuove opportunità di lavoro, esse si concentrano in settori avanzati che potrebbero non essere facilmente accessibili ai migranti a causa della mancanza di programmi di formazione adeguati. (Kerwin, 2020) È quindi fondamentale che le istituzioni attuino iniziative di formazione incentrate sui migranti che non solo forniscano le competenze tecniche necessarie nei settori ad alta tecnologia, ma promuovano anche l'integrazione culturale e linguistica. Tuttavia, c'è il rischio che le iniziative specifiche di genere possano indirizzare le donne migranti verso settori stereotipati come la moda e il cucito, limitando la loro partecipazione a settori più innovativi e tecnologicamente avanzati. (Solano, 2023) L'attuazione di corsi di formazione specifici per i migranti incentrati sulle tecnologie avanzate potrebbe attrarre i migranti che hanno già elevate competenze tecniche.

La digitalizzazione, inoltre, offre alle imprenditrici migranti strumenti preziosi per mantenere e rafforzare i legami con i propri cari rimasti nel paese di origine. Le barriere dovute alla distanza possono essere superate attraverso sistemi di videochiamate che permettono loro di restare in costante contatto con le famiglie e le reti di supporto. La letteratura, ha inoltre evidenziato l'importanza dell'utilizzo dei social network e il ruolo della clientela prevalentemente femminile nel rendere il lavoro delle imprenditrici migranti più sicuro, sottolineando come le piattaforme digitali possano servire non solo per il marketing e la vendita ma anche come strumenti di empowerment e protezione. Questo non solo fornisce un sostegno emotivo cruciale, ma facilita anche la condivisione di conoscenze e risorse che possono essere estremamente importanti per l'avvio e la gestione delle loro imprese. Tale capacità di rimanere connessi non solo rafforza il tessuto sociale tra i paesi ma apre anche opportunità di business transnazionali, sfruttando i legami familiari ed etnici per esplorare nuovi mercati.

In aggiunta, le strategie adottate dalle imprenditrici per agire in contesti a rischio, come l'avvio di attività commerciali in sobborghi sicuri o l'impiego di figure maschili per gestire le operazioni quotidiane, rappresentano pratiche efficaci per mitigare i rischi connessi alla xenofobia. (Oumlil, 2023)

Purpose of the paper. Lo scopo di questo studio è quello di colmare una specifica lacuna nella letteratura esistente, esplorando in modo approfondito l'imprenditorialità migrante femminile all'interno delle aziende familiari. Attraverso l'esame dettagliato delle esperienze di dieci imprenditrici migranti, lo studio mira a identificare e comprendere i fattori contestuali, familiari e individuali che possono agevolare o impedire il loro successo imprenditoriale. La ricerca si propone di esplorare in modo critico come queste imprenditrici navigano tra le sfide e le opportunità nel loro percorso imprenditoriale, ponendo particolare enfasi sul ruolo del capitale sociale e sulle reti di supporto familiare ed etnico.

Attraverso un approccio metodologico qualitativo, basato su interviste approfondite, il presente lavoro cerca di offrire nuove prospettive sull'importanza delle dinamiche interne e esterne alle aziende familiari gestite da donne migranti. Questo lavoro si avvale della teoria dell'embeddedness come framework interpretativo per analizzare le esperienze delle imprenditrici migranti. Tale teoria, che enfatizza l'importanza del contesto sociale, economico e culturale in cui le imprese sono radicate, ha guidato l'elaborazione delle domande di intervista e l'interpretazione dei dati raccolti. Attraverso questo approccio teorico, si è cercato di comprendere come le relazioni personali e professionali, insieme alle condizioni socio-economiche e culturali, influenzino le decisioni imprenditoriali e il successo delle attività guidate da donne migranti.

Inoltre, il lavoro intende contribuire alla letteratura sull'imprenditorialità migrante evidenziando strategie efficaci e potenziali barriere, con l'obiettivo di suggerire politiche e programmi specifici che sostengano e promuovano l'imprenditorialità femminile migrante, consentendo a queste donne di raggiungere il successo imprenditoriale e

contribuire al tessuto economico e sociale delle comunità ospitanti. In particolare, le politiche di ricongiungimento familiare si rivelano essenziali, fornendo alle imprenditrici migranti il supporto indispensabile per avere successo in un contesto imprenditoriale competitivo e sconosciuto. La ricerca si pone, quindi, come un ponte tra teoria e pratica, cercando di evidenziare percorsi di successo e aree di miglioramento nel contesto dell'imprenditorialità migrante femminile.

Methodology. *Questo studio adotta un approccio di studio multi caso per esaminare in dettaglio le esperienze di dieci imprenditrici migranti, tutte attivamente coinvolte in aziende familiari all'interno della stessa regione italiana. Il campione è costituito da donne provenienti da diverse nazionalità, il che introduce una vasta gamma di background culturali e professionali. Con un'istruzione media elevata, il 70% delle partecipanti vanta un Master, mentre il 30% ha una laurea triennale. L'età media del gruppo è di 44,1 anni, segnalando un livello di maturità professionale che promette una ricchezza di esperienze e competenze. Dal punto di vista familiare, il campione mostra una divisione interessante: il 60% delle imprenditrici non ha figli, evidenziando potenzialmente minori vincoli personali, mentre il restante 40% ha due o più figli, suggerendo una complessità aggiuntiva nella gestione dell'equilibrio tra vita professionale e responsabilità familiari. Lo stato civile delle partecipanti si divide equamente, con il 60% sposato e il 40% single.*

La selezione mirata delle intervistate è stata basata sul loro significativo ruolo all'interno delle aziende familiari, assicurando che tutte fossero impegnate in posizioni di leadership o comunque apicali per l'attività. Al fine di rispettare i principi etici fondamentali, abbiamo ottenuto il consenso informato da ciascuna imprenditrice, garantendo la riservatezza e l'anonimato dei dati raccolti. Le interviste sono state condotte di persona, in inglese, per superare le barriere linguistiche e assicurare una comunicazione chiara. Questa scelta ha permesso una discussione fluida e aperta, offrendo alle partecipanti la possibilità di esprimersi liberamente e senza fraintendimenti.

La documentazione raccolta, sia primaria (interviste) che secondaria (relazioni aziendali, siti web, social media, e articoli di stampa), ha fornito una base di dati ricca e variegata per l'analisi. Adottando un approccio induttivo, due codificatori indipendenti hanno analizzato il materiale, identificando temi emergenti e conducendo un'analisi incrociata per evidenziare modelli e divergenze tra i casi. Qualsiasi potenziale discrepanza nell'interpretazione dei dati sarebbe stata risolta con il parere di un terzo codificatore. Tuttavia, la coerenza delle analisi ha precluso la necessità di tale misura, confermando l'oggettività del processo di codifica.

Results. *I risultati dello studio evidenziano l'importanza delle interazioni tra contesto, famiglia e livello individuale nell'imprenditorialità femminile migrante. La combinazione di queste dimensioni crea delle esperienze uniche che influenzano profondamente il percorso imprenditoriale di ciascuna donna. Queste diversità hanno portato a due prospettive sulle azioni imprenditoriali: una incentrata sull'individuo e l'altra sull'azienda. In particola il contesto può essere percepito come amichevole (“Prospero in un ambiente che mi accoglie calorosamente mentre costruisco i miei sogni in questa comunità amichevole!”) o ostile (“Sento che la mia presenza qui non è gradita”), la famiglia come solidale (“La mia famiglia è unita dall'amore, colmando le distanze con calore e sostegno alla mia iniziativa imprenditoriale”) o non solidale (“...la mia famiglia è lontana, quindi capisco di non poter ottenere un vero aiuto, ma non ricevo nemmeno una parola di incoraggiamento da loro, e questo mi rende triste”), e il livello individuale può essere caratterizzato da un'alta autostima (“Credo in me stessa e navigo con fiducia la mia sfida imprenditoriale, trasformando le difficoltà in opportunità”) o da una bassa autostima (“Non sono sicura delle mie abilità, ma mi sforzo di superare la mia mancanza di fiducia mentre affronto la sfida imprenditoriale”). Sulla base di queste percezioni, le imprenditrici migranti formulano una risposta cognitiva specifica, intenzionale o meno, facendo leva su azioni imprenditoriali ben definite, centrate sull'individuo (“Spesso, mi sento sola contro tutti. C'è sfiducia qui, e la mia famiglia è lontana (...) Per affrontare queste sfide, sto lavorando su me stessa. (...) Frequento corsi per specializzarmi, mi sforzo di acquisire ancora più competenze (...) per dimostrare a me stessa e agli altri che valgo.”) o sull'azienda (“Sento di avere una base solida su cui continuare a crescere la mia attività. La mia famiglia mi sostiene, sono apprezzata qui, e mi sento forte, come una leonessa. (...) La mia attività crescerà ancora di più.”). Queste risposte sembrano essere il risultato di specifiche soft skills esibite dalle donne durante le loro narrazioni. I risultati esposti in questo studio forniscono una panoramica significativa delle sfide e delle opportunità incontrate dalle imprenditrici migranti. È importante notare che questa ricerca è attualmente un work in progress. Progetti futuri includeranno l'ampliamento del campione di studio e un'indagine più approfondita sulle implicazioni teoriche e pratiche delle nostre scoperte.*

Research limitations. *Sebbene lo studio mostri intuizioni interessanti, è importante riconoscere alcune limitazioni che ne circoscrivono la portata e la generalizzabilità. La prima limitazione riguarda la dimensione del campione, con soli dieci interviste la rappresentatività è limitata, il che può restringere la capacità di generalizzare i risultati a un contesto più ampio. Nonostante le esperienze dettagliate forniscano approfondimenti significativi, studi futuri potrebbero beneficiare dell'inclusione di un numero maggiore di partecipanti per potenziare e confermare i risultati dello studio.*

Un secondo aspetto da prendere in considerazione è l'assenza di un'analisi approfondita sugli effetti delle dimensioni aziendali. Lo studio non ha esplorato in dettaglio come le diverse dimensioni aziendali possano influenzare le dinamiche imprenditoriali individuate. Questo rappresenta una variabile da considerare nelle ricerche future, in quanto una comprensione più ampia di queste relazioni potrebbe offrire ulteriori spunti per il sostegno e lo sviluppo dell'imprenditorialità femminile migrante.

Un ulteriore aspetto, la concentrazione su una regione specifica dell'Italia, sebbene abbia permesso un'indagine approfondita, limita la generalizzabilità dei risultati ad altri contesti geografici. Le particolarità culturali, economiche e sociali della regione esaminata possono aver influito sulle esperienze delle imprenditrici in modi che potrebbero non essere replicabili altrove. Pertanto, è auspicabile che ricerche future esplorino l'imprenditorialità femminile migrante in diverse aree geografiche per valutare la consistenza delle nostre scoperte attraverso vari contesti.

Infine, un'ulteriore area di indagine che emerge particolarmente rilevante riguarda l'analisi comparativa sull'ambientamento delle donne migranti di una stessa nazionalità nei diversi paesi di destinazione. Lo studio non ha approfondito come specifiche comunità nazionali affrontano e si adattano alle sfide imprenditoriali nei contesti in cui si trasferiscono. Pertanto, sarebbe di grande interesse per le ricerche future esaminare in modo più dettagliato come le imprenditrici migranti, provenienti da uno stesso paese di origine, si inseriscono nell'ecosistema imprenditoriale e sociale dei loro paesi ospitanti.

Managerial implications. *I risultati dello studio forniscono un supporto significativo alle imprenditrici e alle professioniste migranti, comprese le consulenti e le altre titolari d'impresa, offrendo indicazioni preziose sui fattori che possono favorire o ostacolare i comportamenti imprenditoriali. Prevedendo le potenziali preoccupazioni e i problemi, in particolare le barriere contestuali, familiari e individuali, le imprenditrici migranti possono affrontare efficacemente le sfide all'interno delle aziende familiari transnazionali.*

È fondamentale sottolineare il vantaggio che le aziende familiari transnazionali possano trarre dal mantenimento di legami commerciali non solo con il proprio Paese d'origine ma anche esplorando nuovi mercati. Grazie alle loro esperienze di vita uniche, i migranti si trovano in una posizione privilegiata per gestire e sviluppare attività imprenditoriali che superano i confini nazionali. Tuttavia, gli studiosi hanno evidenziato che le esperienze migratorie, pur essendo una risorsa potenziale, non garantisce automaticamente il successo imprenditoriale. È pertanto necessario che le imprenditrici migranti siano supportate con programmi di formazione all'imprenditoria che riconoscano e valorizzino le loro conoscenze e competenze specifiche, includendo moduli dedicati alla gestione delle attività transfrontaliere, all'accesso a reti internazionali e alla comprensione delle varie normative commerciali, potenziando così la loro capacità di massimizzare le risorse a disposizione.

I risultati dello studio enfatizzano anche la necessità di un'analisi più sfumata che riconosca la diversità delle esperienze migranti, sottolineando l'importanza di evitare generalizzazioni. (Mittmasser, 2022) Inoltre, il ruolo critico dei politici è fondamentale nell'implementazione di misure proattive che favoriscano programmi di formazione all'imprenditorialità su misura, essenziali per potenziare le capacità individuali e mitigare gli impatti di ambienti sfidanti.

L'importanza delle politiche di ricongiungimento familiare svolge un ruolo fondamentale nel supportare queste donne a superare le barriere familiari, che spesso rappresentano un ostacolo significativo al loro percorso imprenditoriale. La possibilità del ricongiungimento familiare non solo offre un supporto emotivo indispensabile ma anche una maggiore stabilità e sicurezza, elementi cruciali per l'avviamento e la crescita di imprese in un paese straniero. Tuttavia, il ricongiungimento familiare porta a volte a restrizioni aggiuntive, specialmente in contesti dove la presenza fisica di membri della famiglia, può comportare limitazioni culturali o sociali. In tali situazioni, potrebbe essere preferibile incentivare programmi che promuovano un uso efficace dei social media per mantenere i legami familiari. Questa strategia permetterebbe di evitare le restrizioni che possono sorgere dal ricongiungimento fisico, offrendo alle donne migranti la possibilità di mantenere relazioni familiari stabili e di supporto attraverso la comunicazione digitale, senza incontrare gli ostacoli imposti da determinate norme culturali.

Allo stesso modo, la semplificazione delle procedure burocratiche relative all'avvio e alla gestione di imprese può ridurre significativamente il carico amministrativo, consentendo loro di concentrarsi maggiormente sullo sviluppo e l'espansione delle loro attività.

Un ulteriore aspetto cruciale evidenziato dallo studio riguarda l'importanza del sostegno fornito all'interno delle imprese sociali gestite da donne migranti. Queste realtà non solo facilitano l'ingresso delle nuove imprenditrici nel mercato ma offrono anche un supporto emotivo fondamentale, specialmente in momenti di vulnerabilità personale come il divorzio o la perdita del coniuge. L'esistenza di queste reti di supporto dimostra come la solidarietà femminile possa superare i confini professionali, rafforzando il benessere e la resilienza delle imprenditrici. Di conseguenza, è essenziale che le politiche favoriscano la creazione e lo sviluppo di queste iniziative, facilitando l'accesso a finanziamenti e benefici fiscali, per sostenere l'integrazione e il successo delle imprenditrici migranti nei tessuti economici locali e contribuire al loro benessere personale.

Originality of the paper. *Questo studio si distingue dalle ricerche precedenti, che spesso hanno trattato separatamente il contesto e il livello individuale, evidenziando invece la loro interconnessione e coesistenza. In particolare, questa ricerca approfondisce le esperienze delle imprenditrici migranti affermate nel contesto delle imprese familiari, il che aggiunge complessità alle loro interazioni con ambienti multipli - il loro Paese d'origine e il Paese ospitante. Attraverso questo approccio, si offre una prospettiva unica per comprendere le percezioni sfumate del contesto, variando dalla cordialità all'ostilità. Le dinamiche cognitive rivelate, strettamente legate alle dinamiche dell'azienda familiare, illustrano le strategie di adattamento impiegate da questi imprenditori per affrontare le sfide e raggiungere il successo. Incrociando l'ambito dell'azienda familiare con fattori personali e contestuali, il presente studio arricchisce la comprensione di come le imprenditrici migranti di successo manovrino attraverso le complesse dinamiche di interazione, illuminando il loro percorso imprenditoriale distintivo tra diversi contesti culturali e commerciali.*

When algorithms help cross-cultural management educators: a proposed supportive tool

BICE DELLA PIANA¹ FRANCESCO DI VINCENZO² CHIARA SIGNORE³ MARIO TREROTOLA⁴

Abstract

This study explores the conceptualization and design of a supportive tool aiming at assessing the student Cross-Cultural Competence (CCC) within the context of higher education. Employing Principal Component Analysis (PCA) and non-hierarchical Cluster Analysis (non-HCA), the research aims to discern patterns and similarities in student data to aid in the conceptualization of the supportive tool for cross-cultural management educators. It coherently to the relevant literature discourse examines the impact of several factors, including experiences in foreign countries and participation in academic courses with a cross-cultural emphasis. This algorithm is also designed to assist in creating tailored strategies for enhancing students' CCC by exploiting identified cluster compositions. Data was gathered through a specifically designed survey based on literary research orientations and distributed to students across bachelor's and master's degree programs at the University of Salerno. The PCA identified three principal components exerting a significant influence on students' capability to navigate diverse cultural environments. Subsequent non-HCA defined distinct student traits, thereby providing deeper insights into the assessment of CCC. The algorithm, based upon these statistical methodologies, can enhance the automation of future survey analyses across diverse contexts. This advancement provides cross-cultural management educators with a supportive tool for fostering CCC through the deployment of customized educational strategies, tailored to the unique attributes of the students.

Key words: principal component analysis; non-hierarchical cluster analysis; assessment; cross-cultural competence; cultural intelligence; algorithm

Framing of the research. *In the evolving landscape of higher education, the imperative to cultivate cross-cultural competence (CCC) among students has never been more pronounced. The university environment emerges as a critical opportunity for the CCC education among students, equipping them with the requisite skills to effectively engage in international contexts. CCC has been defined by Gertsen (1990) as the ability of individuals to function effectively within the context of another culture. Cross-cultural training programs frequently focus on elements conducive to brief instructional periods, such as specific behavioral skills and knowledge that can be readily assessed, often at the expense of a more comprehensive cultural understanding and the development of metacognitive abilities (Johnson et al., 2006). Earley & Ang (2003) broadened the conventional notion of CCC, incorporating cognitive, behavioral, and motivational dimensions but also a metacognitive component, thereby introducing the concept of CQ. It has been defined as the ability of individuals to effectively navigate and manage interactions within culturally diverse environments (Earley & Ang, 2003) and this construct provides insight into variance in intercultural competence (Eisenberg et al., 2013). The CQ is a multidimensional construct aggregated from four dimensions representing different capabilities. Cognitive CQ regard explicit knowledge of values, norms, and practices in various cultures (Earley & Ang, 2003). It also includes knowledge of the social, economic, and legal systems of different cultures. Metacognitive CQ refers to an individual's level of conscious cultural awareness and it relies on advanced cognitive strategies and in-depth information processing (Van Dyne et al., 2012). This dimension is associated with awareness of others' cultural preferences and intentions both before and during cross-cultural interaction. Motivational CQ reflects the ability to direct attention and energy toward learning about and performing effectively in situations marked by cultural differences (Ang et al., 2007). A high level of motivational CQ enables individuals to more effectively manage both the emotional and cognitive aspects of multicultural situations, which can often generate uncertainty and anxiety (Van Dyne et al., 2012). Furthermore, they demonstrate a keen interest in learning about various aspects of different cultures and display increased confidence in adapting to culturally diverse situations (Eisenberg et al., 2013). The last dimension, the behavioral CQ refers to the ability to display*

suitable verbal and non-verbal behaviors when interacting with culturally diverse individuals. It includes a wide and adaptable range of behaviors, including aspects such as tone, gestures, personal space, dress codes, and time management, which are appropriate for intercultural interactions (Eisenberg et al., 2013). The development of culturally intelligent resources is achievable through a positive approach towards diversity, with cross-cultural educators playing a pivotal role in fostering effective interactions among individuals from varied cultural backgrounds. CQ is dynamic, and individuals can enhance their competences through a range of strategies, including training and coaching programs, personalized development plans, or, most significantly, through direct experiences where participants are immersed in a culturally distinct environment (Rand, 2015). Griffith et al. (2016) highlighted different evidence of reliability and validity of intercultural competence assessment including the Cultural Intelligence Scale (CQS) (Ang et al., 2007). The internationalization of academic curricula and exposure to diverse cultures have been instrumental in creating opportunities for significant transformations in education and learning, thereby enhancing international cross-fertilization, but to understand how to develop customized strategies tailored to the unique needs of students, it is essential to identify common patterns of characteristics that enable the definition of objectives for each student group.

Purpose of the paper. The purpose of the paper is search for similarities and hidden patterns between students, using PCA and a non-HCA to identify key components contributing to CCC of the students to develop a technological tool: an algorithm designed to serve as an auxiliary resource for cross-cultural educators. This algorithm aims to facilitate the formulation of targeted strategies for the future enhancement of CCC among students, by interpreting and applying the patterns that delineate the compositions of identified clusters thought the analysis of the impact of study abroad experiences, the number of countries visited, and participation in cross-cultural related courses.

Methodology. During the four-year period 2019-2022, a questionnaire was administered by the 3CLab - Cross Cultural Competence Learning and Education research lab at the University of Salerno with the aim of measuring the CQ level of university students. The survey was implemented via the CAWI (Computer Assisted Web Interviewing) approach. The choice of this methodology stems from the possibility of constructing a tailor-made questionnaire, asking questions targeted to the research objectives through a clear, easy-to-complete interface that can be used at anytime and anywhere in the world (Amaturo, 2012). The research sample consisted of university students enrolled in both bachelor's and master's degree courses.

The questionnaire is divided into three different sections. The first part of the form includes questions referring to socio-demographic information of the respondents: gender, age, country of origin, country where the pre-university education was completed to ascertain whether it was conducted abroad. The second part is aimed at investigating the enabling factors for the development of students' CCC. Based on the literature, it was determined that the questionnaire should incorporate a question about experiences abroad lasting at least one month. Several studies have been interested in the results obtained from short-term experiences (Chieffo & Griffiths, 2004; Dwyer, 2004) and according to Fowers and Davidov (2006), there is strong evidence of the effectiveness of this type of experience in promoting intercultural interest, knowledge, and cultural awareness. Moreover, having visited different countries also appears to be an additional factor conditioning CCC. For this reason, students were asked to indicate the number of countries they had visited. The questionnaire also includes questions regarding whether students attended a specific course related to cross-cultural topics. Several studies have highlighted the positive impact that courses focused on cross-cultural issues can have improving students' CQ levels (Ramsey & Lorenz, 2016; Eisenberg et al., 2013; MacNab, 2012). The survey concludes with the self-assessment model developed by Ang et al. (2007), the CQS which allows us to define the students' CQ level. It consists of 20 items, sorted by the four dimensions of Cultural Intelligence (Metacognitive, Cognitive, Motivational and Behavioral), which define the overall CQ score and level for each dimension. Using a seven-mode Likert scale, students define their degree of agreement/disagreement with the proposed statements following the model of Van Dyne et al. (2015), whose research has supported the predictive validity of CQ with student self-reported measures. To develop the CQS, Ang et al. (2007) reviewed the literature on CQ and intercultural competence. They supplemented it with the contribution of several interviews with eight managers with extensive global experience. Different fields of study were used to determine the specific items. In particular, the authors referred to educational and cognitive psychology (O'Neil & Abedi, 1996), which assesses the awareness, planning, regulation, monitoring, and control of cognitive thinking and learning processes; the Human Relation Areas (Murdock's, 1987; Triandis, 1994), including the economic, legal and social systems of other cultures; the intrinsic satisfaction theory (Deci & Ryan, 1985), auto-efficacy in the intercultural context theory (Bandura, 2002) and intercultural communication for verbal and non-verbal flexibility (Hall, 1959; Gudykunst et al., 1988) were also assessed. The authors (Ang et al., 2007) demonstrated a good fit of the scale between the four-factor model and a sample of Singapore university students. Furthermore, they verified the reliability of the scale with three different studies. A first study provided cross-validation of the Cultural Intelligence Scale (CQS) across different samples, a second study assessed its generalization over time through cross-validation with a subset of respondents four months apart, and the last study assessed generalization with a cross-comparison of a sample from the United States versus the Singapore sample. A validation analysis of the scale was also conducted regarding the Italian version of the 20 items, providing further empirical support for the reliability of the CQS and the consistency of the four specific dimensions of cultural intelligence (Gozzoli & Gazzaroli, 2018).

The sample under consideration in this study comprises 137 individuals. The gender distribution within the sample includes 81 female and 56 male respondents. Age-wise, the sample is segmented as follows: approximately 48.18% of the individuals are aged between 18 to 22 years, 40.88% are within the 23 to 26 age brackets, 7.30% fall into the 27 to 30 range, and 3.65% are older than 30 years. These percentages offer a detailed view of the age composition of the sample. Regarding nationality, the sample features a broad diversity, encompassing n.3 individuals from Armenia, n.1 from

Belarus, n.1 from the Czech Republic, n.6 from Finland, n.1 from Greece, n.1 from Hungary, n.9 from India, n.105 from Italy, n.5 from Romania, n.1 from Spain, n.1 from Uganda, and n.3 from Ukraine.

The Principal Component Analysis (PCA) is a multivariate data analysis technique used to study, explore, and represent the variation present in the dataset using a small number of factors (PC). This allows the identification of one or more latent PCs that capture the similarities between the variables (Barbaranelli & D'Olimpio, 2006). It's a powerful tool to examine the correlation among variables in the dataset. It is based on the direct calculation of eigenvalues and eigenvectors with the aim of replacing the old observed variables with new variables that are a linear combination of the former that summarize their information. The components thus represent linear combinations of the original variables explaining the maximum variance (i.e. summarizing as much information as possible of the original variables) (Barbaranelli & D'Olimpio, 2006).

The analyses were conducted using SPSS software in its version 29 and the list of the variables selected from the survey to conduct the PCA are presented in Table 1. The number of PCs to be extracted has been defined by the Kaiser criterion (Kaiser, 1960; Barbaranelli & D'Olimpio, 2006): eigenvalue higher than 1 are considered significant in the PCA. A Varimax type rotation (maximum interaction for coverage equal to 250) with Kaiser normalization has been applied to the variables so that the PCs calculated are linear combinations of the original variables. In addition, the Kaiser-Meyer-Olkin (KMO) and Bartlett's test of sphericity indicate that the model is adequate (Kaiser, 1970; 1974; Bartlett, 1954). Among the various solutions documented in the literature, the cluster analysis was performed using the k-means methodology. This is the most widespread non-hierarchical clustering method (Barbaranelli & D'Olimpio, 2006) and involves solving an algorithm for minimizing the distances between all possible centroids. It is a point-based clustering approach that initiates with the cluster centers positioned arbitrarily and continues by iteratively relocating the cluster centers at each step to reduce the clustering error (Likas et al., 2003). It produces changes in the partition by moving objects from one cluster to another based on Euclidean distance. The assignment of individual objects to groups is done in a way that maximizes the ratio between the "between-groups" variability and the "within-groups" variability, according to the criterion of "minimum variability within groups" and "maximum variability between groups" (Barbaranelli & D'Olimpio, 2006).

Table 1. Variables

Variables	Type	Information acquired
Education Abroad	Dichotomous variable 1: Different; 0: Equal	Whether the respondent pursued their non-college education abroad.
Period Abroad	Dichotomous variable 1: Yes; 0: No	Assessment of the duration of time spent abroad, with a minimum period of one month.
Number of countries visited	Nominal variable 1: 0-3; 2: 4-7 countries; 3: >8 countries	Evaluation of the total number of countries visited.
Cross-cultural courses attended	Dichotomous variable 1: Yes; 0: No	Respondent's attendance of at least one cross-cultural management, competence, or similar course
Mot CQ	Likert scale (1-7)	Motivational dimension of CQ
Cog CQ	Likert scale (1-7)	Cognitive dimension of CQ
Meta CQ	Likert scale (1-7)	Metacognitive dimension of CQ
Beh CQ	Likert scale (1-7)	Behavioral dimension of CQ

Results. The main results of our research are organized as follows. The first session is about the results of the PCA and non-HCA; the second session is focused on the formalized algorithm.

PCA and non-HCA results

Descriptive statistics regarding this sample are detailed in Table 2.

Table 2. Descriptive statistics

	Minimum	Maximum	Mean	Std. Deviation	Variance
Date	2019	2022	2020.31	.765	.585
Sex	0	1	.41	.493	.243
Age	0	3	.66	.770	.592
Cross-cultural courses attended	0	1	.19	.394	.155
Attended school	0	1	.07	.249	.062
Number of countries visited	1	3	1.55	.663	.440
Period Abroad	0	1	.32	.469	.220
Meta CQ	1.00	7.00	4.9307	1.23771	1.532
Cog CQ	1.00	7.00	4.06569	1.23972	1.537
Mot CQ	1.0	7.00	5.591	1.1378	1.295
Beh CQ	1.0	7.00	4.745	1.3741	1.888
CQ Overall	1.00	7.00	4.7898	.95452	.911

In our dataset, the eigenvalue continues to have a value >1 where it indicates 3 components representing a total variance of approximately 62%. For this region, it was decided to perform PCA with a 3-factor model (Table 3). Since the original variables may exist on various measurement scales, they are typically centered and scaled. KMO's values is close to the threshold value 0.7 representing the presence of sufficient correlation between the variables and the Barlett's test of sphericity is significant (Table 4). This constitutes an inferential test aimed at determining whether the variables are independent. Since the results of the test prove to be significant, it confirms the feasibility of a PCA. In summary, the PCA has revealed a model that consists of three distinct PCs. In the process of obtaining the rotated component matrix, which elucidates the composition of the PCs as presented in Table 5, we have excluded cross-loadings below 0.3 and grouped the factors by size.

Therefore, these PCs were analyzed to ascertain their impact on cross-cultural competence: Component 1 encompass the 4 dimensions of the CQ (as expected given the validation of the CQS above mentioned). Component 2 includes both the duration of time spent abroad for at least one month and the total number of countries visited. The latter, Component 3, consists of participation in cross-cultural training courses and includes any form of pre-university education undertaken in a foreign country. This three new PCs were saved in SPSS and normalized using the regression method to allow aggregate values and subsequent analyses: non-HCA.

Table 3. Total Variance Explained and application of the Kaiser criterion.

Component	Total	Initial Eigenvalues		Extraction Sums of Squared Loadings			Rotation Sum Squared Loadings		
		% of Variance	Cumulative %	Total	% of Variance	Cumulative %	Total	% of Variance	Cumulative %
1	2.437	30.458	30.458	2.437	30.458	30.458	2.357	29.465	29.465

Attended school			.702

Based on the PCA conducted, we used the PCs as new variables to proceed with the definition of the clusters. To ascertain the optimal number of clusters, we empirically calculated and interpreted the pseudo-F statistic, which reaches its maximum value corresponding to the optimal cluster number (Calinski et al., 1974). The pseudo-F statistic has been computed as the ratio between the sum of the mean squares of the clusters and the mean square of the error, and it refers to the test statistic used to evaluate the overall significance of a cluster model. This type of test is associated with the analysis of variance (ANOVA) and is utilized to assess whether there are significant differences between the groups of data created through clustering maximizing the differences among cases in the different clusters. The hypothesis positing four clusters exhibited a score of 65.28, the highest among all other options considered (figure 1), and Table 6 displays that the model's significant. The four determined clusters are composed of, respectively, 55, 40, 29, and 13 units.

Table 6. Anova

	Cluster		Error		F	Sig.
	Mean square	df	Mean square	df		
Component 1	23.269	3	.498	133	46.755	<.001
Component 2	31.108	3	.321	133	96.648	<.001
Component 3	26.635	3	.422	133	63.151	<.001

Figure 1. Progression of Pseudo-F Statistical Measures

The findings of this study reveal the development and validation of a three-factor tool derived from the PCA, which facilitates a nuanced understanding of CCC among university students. This innovative approach delineates the intricate PCs, enabling a detailed exploration of the constituents of cultural competence. Subsequently, through the application of k-means cluster analysis, the research methodology allows for the identification of distinct profiles within the student population. Our classification based on the identified PCs allowed us to determine 4 clusters that uncovers common patterns among subsets of the population, shedding light on the variegated landscape of CCC within a diverse academic cohort. The four clusters exhibit distinct characteristics as depicted in Figure 3. Specifically, the subjects within Cluster 1 (n.55), have been grouped together due to their significantly higher levels of CQ compared to the other components. This could suggest that for these students, it might prove beneficial to plan activities to be carried out abroad and participation in CCC training. Conversely, Cluster 2 comprises 40 subjects who exhibit low levels across all PCs, particularly about the CQ and the experience abroad. This indicates that rather than participation in CCC courses, it would be beneficial to engage mechanisms capable of enhancing the overall level of CQ and to recommend their participation in programs, such as Erasmus, to effectively improve their CCC. Cluster 3 is distinguished by 29 subjects who excel notably in their experiences abroad. This cluster indicates the necessity for these individuals to formalize their experiences through specific CCC related courses to also increase their own CQ. Suggesting new experiences abroad would be superfluous. The latter cluster represents a “niche” group of subjects, evidenced by its smaller size relative to the others (n.13). These are students who have reported significant levels across all three detected PCs.

Figure 2. Final Cluster Centers

The proposed algorithm as supportive tool for cross cultural management educator

This methodology was outlined as a supportive tool through an algorithm that can help cross-cultural management educators. Figure 3 shows the pseudocode that delineates the proposed algorithm that initially applies PCA to the normalized dataset to identify the main axes of variance. It employs statistical tests-KMO and Bartlett’s-to verify the

data's suitability for PCA. On meeting the threshold criteria, it extracts significant components, applies varimax rotation to maximize variance, and computes component scores. Subsequently, it performs k-means clustering to partition the data into optimal clusters, determined by a pseudo-F statistic. The final output presents the clustered data. Employing these statistical methodologies, the presented algorithm significantly contributes to the automation of analytical processes in survey research across a spectrum of contexts. It can help the deployment of specific strategies that are intricately customized to align with the distinct characteristics and cultural backgrounds of the students, thereby enhancing educational outcomes in a cross-cultural framework.

Research limitations. The research is conducted on a unique sample collected by the 3CLab – Cross Cultural Competence Learning & Education. The specificity of the sample might limit the generalizability of the findings to other population. In this case, our analysis was confined to a sample of students, predominantly of Italian origin. Expanding the sample, both in terms of cultural diversity and by incorporating the analysis of managers and professionals could prove to be of significant interest for future research endeavors. Such an enlargement of the sample scope would not only enrich the understanding of CCC across different societal sectors but also enhance the generalizability and applicability of our findings to a broader context. Moreover, the selection of variables to be examined was guided by the existing literature on factors capable of influencing CCC, as highlighted in the discussion. However, this approach may not preclude the omission of additional variables that could be beneficial to consider. This algorithm serves as a comprehensive foundation, setting the stage for the future expansion and enhancement of a comprehensive supportive tool designed for cross-cultural management educators, anticipating continuous improvements and expansions in its functionalities.

Managerial implications. This analysis paves the way for the formulation of tailored developmental strategies, aimed at enhancing CCC of students on a cluster-by-cluster basis. The clusters, in terms of composition and size, can vary based on the sample being analyzed, but this methodological setup remains significantly useful for determining different groups

and customizing specific improvement strategies for them. Moreover, the defined algorithm makes it possible to automate these statistical steps to quickly determine the different clusters and thus define customized CCC development strategies. In doing so, the research offers practical implications for the design of targeted interventions to foster CCC among university students and for managers. The strategic application of this three-factor PCA and subsequent cluster analysis exemplifies a forward-thinking approach to educational research, affirming the importance of personalized learning pathways in the cultivation of global citizens equipped to navigate the complexities of a multicultural world.

Originality of the paper. To the best of the authors' knowledge, this represents a first attempt to apply PCA techniques and non-HCA in an algorithm to identify common patterns among students in order to develop and suggest future specific intervention strategies to increase CCC.

Decoding the future: entrepreneurial visions on AI's role in international strategic decisions

BARBARA FRANCONI¹ ALICE AIUDI² YULIIA KYRDODA³ SIMONA AMERIO⁴

Abstract

In an era of rapid digital transformation, AI emerges as a pivotal technology that enhances decision-making processes, productivity, and competitiveness across industries, especially in the international context. The study aims to elucidate how entrepreneurs adopt AI technologies to navigate international strategic decisions (ISDs), focusing mainly on small and medium-sized enterprises (SMEs). The paper presents insights from interviews conducted with CEOs and export managers of an Italian manufacturing SME through a qualitative research approach. Findings suggest a nascent integration of AI within SMEs, primarily delayed by a lack of understanding and trust in AI's capabilities and the considerable investments required for technology adoption and personnel training. Despite these barriers, there is a growing interest in leveraging AI for international market analysis, strategic decision-making, and optimizing operational efficiencies. The paper underlines the critical need for educational initiatives and support mechanisms to increase AI adoption among SMEs, highlighting AI's potential to enhance SMEs' international competitiveness. The study contributes valuable perspectives to the intersection of AI and international business research, encouraging a future in which SMEs use AI to achieve international success and sustainable growth.

Keywords: artificial intelligence; international strategic decision; international market selection; small and medium size enterprises; internationalization.

Framing of the research. *In recent years, the multifaceted digital transformation process has become fundamental to the management debate (Zoppelletto et al., 2023). This phenomenon results from integrating modern technologies that enhance data gathering, archiving, and analysis. Such technologies encompass numerous innovations and state-of-the-art instruments, including robotic automation, additive manufacturing, artificial intelligence (AI), and the Internet of Things (IoT) (Strange et al., 2022). Among them, AI has emerged as a critical facilitator, providing essential opportunities for innovation and growth across a variety of industries by assisting in overcoming computational, logical, and even creative limits that have long limited human activities (Dwivedi et al., 2021; Kumar et al., 2022). The distinctive feature distinguishing AI from other technologies is its capacity to learn, build connections, and adapt, which enables AI systems to continuously enhance and evolve, leveraging the data and experiences they encounter (Brock & Von Wangenheim, 2019).*

A contemporary definition by the OECD (2022, p. 4) characterizes AI as “a machine-based system that can, for a given set of human-defined objectives, make predictions, recommendations, or decisions influencing real or virtual environments with varying levels of autonomy”. The term “AI adoption”, that refers to its acceptance and utilization by society but also to its integration within an organization (Radhakrishnan & Chattopadhyay 2020), leading global companies, like Google and Microsoft, are progressively enhancing their products with AI facilitating widespread access to numerous technologies (Konnerth, 2023). Technologies made possible by AI can be employed to improve operations, products and services, and other aspects of the business, such as corporate performance. AI enables continuous operational refinement through data analysis and insight generation, providing organizations with benefits such as improved decision-making, increased productivity, and competitive advantage (Magistretti et al., 2019; Cheng et al., 2021; Denicolai et al., 2021). Through work automation, data-driven insights, and robust predictive analytics, AI integration helps organizations navigate complex global situations (Bag et al., 2021; Satheesh et al., 2020; Allal-Chérif et al., 2021; 2020; Wamba-Taguimdje et al., 2020).

In the context of international business (IB), AI is one of the major factors driving its evolution. It could be vital in solving intricate problems in this field, enabling businesses to employ adaptive algorithms for tasks previously requiring human intelligence (Ahn et al., 2022). According to Li et al. (2021), Shi (2022), and Zhu (2021), AI enables to anticipate market demands, reduce risks, optimize supply chain management, simplify logistics, and improve cross-border transactions, especially after the launch and public availability of Chat-GPT from Open AI as well as other comparable apps like Google's Bard and Microsoft's Bing. Regarding e-commerce, AI optimizes operations, improving efficiency, and delivers timely and accurate assistance to users by automating responses and interactions through Chatbot applications (Cheng et al., 2021). Due to its accessibility, AI has become more widely accepted and has generated interest in how it will affect the workplace and commercial environment (Menzies et al., 2024), also considering that its influence depends on the type used (Konnerth, 2023).

For these reasons, interdisciplinary research at the nexus of AI and IB is becoming more widespread (Jarrahi, 2018). In this stream of research, according to the OECD Trade Policy Paper (2022), AI has demonstrated the ability to change several facets of global trade and business models, including improved market selection and manufacturing location decision-making (Feliciano-Cestero et al., 2023). Although previous research has focused on the internationalization process of firms, research in the context of AI is comparatively limited (Ratten, Jones & Braga, 2024). Indeed, the study by Jones (2023) emphasizes a need for a comprehensive understanding of the application of AI and related technologies in effectively addressing IB challenges, including its sub-functional areas. Furthermore, the study underlines the necessity of elucidating the connections between AI-enhanced IB functions and other operational activities to optimize organizational outcomes.

For multinational companies (MNEs), adopting AI is becoming fundamental for enhancing productivity, competitiveness, and decision-making capabilities (Bag et al., 2021), especially in the international context. AI can improve MNEs' recognition of foreign opportunities and give them more access to international markets (Dillon et al., 2020). However, while MNEs may face fewer obstacles in handling digital transformation, AI presents fresh prospects for small and medium-sized enterprises (SMEs) by improving their competitiveness (Baabdullah et al., 2021). The benefits of AI implementation encompass the development of new business models and the enhancement of customer and entrepreneur experiences. Furthermore, AI could help SMEs to increase their profitability by advancing advertising, customer service, content writing, conversion optimization, predictive analysis, decision-making, wealth management, and fraud prevention (Enshassi et al., 2024). AI's ability to adapt and remain relevant over time enables SMEs to avoid the risk of becoming reliant on technology that may become outdated and expensive to replace, while also providing business solutions that are more sustainable and cost-effective (Castillo & Taherdoost, 2023).

The European Economic and Social Committee's 2021 study underscores the importance of increasing AI adoption among Europe's SMEs to reinforce their innovation capacities and facilitate their expansion into international markets. This strategic approach enables SMEs to compete effectively on a larger scale. In this respect, AI can help entrepreneurs with important international strategic decisions (ISDs), such as international market selection (IMS). There is a notable interest in this perspective, indicating the need for further research and the development of AI-powered models for market analysis, precise forecasting of foreign market trends, and formulating entry strategies (Menzies et al., 2024).

Notably, IMS is an essential and complex decision-making process where firms choose which markets to target and be present in (Francioni et al., 2015). The literature on international business, marketing, and management has long acknowledged the importance of this strategic decision (e.g., He et al., 2016). Indeed, the variety and diversity of international markets, and the difficulties businesses encounter when locating, assessing, choosing, and seizing opportunities overseas, highlight the strategic significance of IMS. The performance impact (Brouthers et al., 2009; Martín Martín et al., 2022) contributes to the consensus that well-informed IMS decisions result in favorable outcomes. Furthermore, according to Papadopoulos and Martín Martín (2011), there are expenses related to joining the incorrect markets as well as lost chances from not choosing better options. Other significant ISDs related to IMS include choosing an entry mode (Francioni et al., 2015) and, if required, choosing appropriate foreign partners, such as prospective clients, agents, and distributors. Consequently, the global success of SMEs may be significantly impacted by using AI in key ISDs (Denicolai et al., 2021; Kumar et al., 2022). In the footsteps of Fish (2006), who tackled the issue of IMS using AI computing and Kohonon Self-Organizing Maps, an example may be the successful application of Large Language Models, like Chat GPT, to identify an appropriate foreign market for a recently developed product. Like this, AI can help find possible cross-national segments' clusters. This is particularly useful for SMEs, which frequently lack thorough internationalization plans and methodical methods for market selection (Vissak & Francioni, 2013; Musso & Francioni, 2014), as they can use AI to speed up their expansion.

Despite the potential benefits, many SMEs have hesitated to embrace AI technologies due to challenges arising from their size, including limited financial resources and technical expertise (Silva & Gonçalves, 2022). There are numerous obstacles to applying AI in SMEs, including a lack of qualified employees, high expenses, a lack of expertise in the field, a lack of rules, technological issues, etc. Indeed, for a successful AI adoption, barriers related to trust, security, price, management support, and technical competencies need to be overcome (Enshassi et al., 2024).

SMEs frequently underestimate the importance of digital solutions, mainly because entrepreneurs are unaware of their possible advantages (McCann & Barlow, 2015). Therefore, more evidence is needed for SMEs to apply these technologies (Prem, 2019).

Purpose of the paper. Since research on the intersection of AI and IB is still in its early stages and requires a theoretical framework, it is a promising opportunity to explore this field, generating insights and encouraging discussion (Ratten, Jones & Braga, 2024). Therefore, given the overview of previous research, the purpose of this paper is to shed

light on the transformative potential of AI in the global economic landscape and to offer insightful information on how firms, especially SMEs, which are the backbone of the European economy⁵, can take advantage of this technological revolution.

For this reason, this contribution aims to answer the following research question: How do entrepreneurs adopt AI digital technologies in International Strategic Decisions?

Having explored how entrepreneurs in this stream adopt AI technologies in making ISDs, the research question of the present work will be addressed by conducting extensive qualitative research. In particular, based on the suggestion of Ratten, Jones, and Braga (2024), conducting interviews in international businesses will allow us to comprehend their perceptions and thoughts on AI adoption processes. This will be beneficial in proactively shaping future practices and enhancing SMEs' understanding of integrating AI into their ISDs.

Methodology. The study follows a qualitative approach to answer the research question about adopting digital AIs for international strategic choices. In particular, we employed a case study approach, which is highly relevant in international research (Eisenhardt, 1989; Ghauri, 2004; Yin, 2009). In the case of the current study, this methodological framework allows for exploring participants' perceptions regarding the processes of adopting AI in the context of ISD.

Consistent with previous studies (Rashid et al., 2019; Yin, 2009), we carried out the following steps: planning, design, preparation, data collection, analysis, and development of findings. In detail, after outlining the research objectives and questions, a research approach and data collection method have been defined. The interview protocol for the research was divided into three parts: first, a brief introduction aimed at gathering information on the company's profile, including its founding date, location, years of international involvement, and presence in foreign markets. The next set of questions focused on the adaptation of AI within the company to determine the current status of its implementation and managers' perceptions of it. A discussion of AI's potential value and use in various aspects of the international decision-making process, such as market selection, entry modes, partner selection, customer engagement, market performance analysis, logistics optimization, and risk management, followed this. Similar inquiries have been directed to the international sales back office.

Data on Italian manufacturing SMEs that have performed international activities have been collected for research purposes. The decision to target this specific group is due to the dominance of SMEs in the Italian economy, which are particularly well known for their proactive adoption of digital innovations (Matarazzo et al., 2021; Miroshnychenko et al., 2021). Data collection is in progress and, at the moment, primary data were collected through interviews with both the CEO and the export manager of IRON⁶. These interviews, which lasted between 30 and 45 minutes each, were recorded with the consent of the participants. Specifically, the business under analysis is an SME that specializes in contract metalworking operating in the Marche region's hinterland. The CEO, who over the years has taken on more and more responsibility for strategic business growth decisions, particularly those involving internationalization, was interviewed to achieve the goal of this research. Generally speaking, exports account for 20% of the company's turnover.

As the case study approach highlights the importance of integrating multiple sources of evidence, additional available materials, such as company reports and online resources, have been added. The secondary data was collected prior to the interviews to facilitate the data triangulation (Eisenhardt, 1989). In line with previous research (Pagani & Pardo, 2017), we considered reliability by elaborating a detailed case study protocol and performing member checks. This step ensures a higher degree of accuracy with less subjectivity in the interpretation of the findings and integrating the researchers' suggestions into the theoretical evidence (Ranfagni et al., 2021).

In the data analysis stage, we followed a ground-up approach based on extracting the theoretical themes from the obtained data from analyzed cases (Ghauri, 2004; Yin, 2009).

Results.

AI adoption - During the interview, the authors asked whether the company was already using AI directly or with the help of consultants. The CEO gave the following answer:

'At the moment, we are not yet using any kind of artificial intelligence tools directly. I am beginning to inform myself and to study what the tools might be and how I might incorporate them to take advantage of them. So, as a CEO, I am considering doing that in the future. I am working with an external consultant who deals with innovation and digitization, and with him, we are participating in calls to win funding related to the development of advanced digitization platforms but with a view to improving some processes that are more critical and problematic for us such as logistics (both internal and external). However, I am also thinking of involving others to implement AI-based solutions in internal strategic departments.'

Therefore, it appears that the company sees it as a potential future opportunity and that the current lack of usage is mainly attributed to the lack of information, as stated by the CEO:

'We have not used them yet because we do not have an in-depth knowledge of what these tools are and how they can be used, and therefore major investments would be needed both to have the same solutions and for the training that would have to follow.'

⁵ [https://single-market-economy.ec.europa.eu/smes_en#:~:text=Small%20and%20medium%2D-sized%20enterprises%20\(SMEs\)%20are%20the%20backbone, every%20sector%20of%20the%20economy](https://single-market-economy.ec.europa.eu/smes_en#:~:text=Small%20and%20medium%2D-sized%20enterprises%20(SMEs)%20are%20the%20backbone, every%20sector%20of%20the%20economy) [22/02/2024]

⁶ The name of the company has been anonymized to ensure confidentiality.

While asking about confidence in the effectiveness of AI, despite showing interest and mentioning some research on the topic, trust emerged as a crucial missing element to proceed further in AI adoption within the company. The CEO said:

'I am reading many articles and success stories related to the engineering industry that use artificial intelligence. However, I must say that I still do not totally trust them. I would also like to hear and evaluate how my competitors work and how they adopt them especially if they are really effective to get totally to trust and seriously think about adopting them in the company.'

However, this was different from the perspective of the Foreign Sales Back Office, who shared that not only is not thinking of adopting AI but also was never really interested in it.

Internationalization and AI - As the company has been internationally involved for more than eight years and operates in five different countries, the focus was on understanding how ISDs are currently made. The CEO explained that the company relies on word of mouth to acquire new customers, depending on foreign customers to refer the company's name to other partners. Even though AI is not currently utilized within the company, there is an expressed interest and potential for its adoption in the future. Referring to AI applications, the CEO said:

'We would be interested in implementing them because I realize there is potential. They could improve our ability to analyze international markets, which at the moment as mentioned is virtually absent, and make informed decisions based on data instead of relying solely on word of mouth from our customers.'

Regarding the benefits of integrating AI into ISDs, it was recognized by the CEO that:

'[...] there is potential to understand foreign markets better. I'm convinced that decisions should only be made if you have enough data and, in this case, since artificial intelligence relies precisely on large databases could help us make certainly more informed decisions at the very least. So maybe the risks associated with poor choices may decrease. [...] I think one of the great advantages of AI is the fact that we have available and continuously process a database that is beyond our capabilities (in terms of human capabilities) so certainly the analysis of foreign markets could be much more optimized. Then clearly the human capacity to be able to evaluate alternatives and make the most sensible decisions based on the information also takes over. Internationalization strategies in general would then be much more reasoned and objective.'

This positive perception toward AI used for ISDs, was also shared by the Foreign Sales Back Office, who said that being able to 'have forecasts of customer demand trends, would be much easier to coordinate production and logistics' improving the company's international business.

Finally, despite the CEO's interest and acknowledgment of the potential benefits associated with AI adoption, there is a clear and pressing need for a comprehensive understanding of AI applications and their integration within the company (e.g. *'[...] However, I would first like to be certain by studying more that these are the right tools for our needs.'*). Both the Foreign Sales Back Office and the company's CEO expressed a lack of knowledge about AI and admitted to being unfamiliar with its tools.

Based on these initial interviews, it is evident that this paper holds relevance and will prove valuable for SMEs seeking insights into adopting AI digital technologies. The topic remains somewhat obscure and needs further exploration. Through future interviews showcasing how some entrepreneurs are already incorporating AI into their ISDs, this paper will make a meaningful contribution.

Based on the comprehensive insights provided in the paper, it is evident that the adoption of AI holds transformative potential for SMEs, particularly in the context of ISDs. The first qualitative interviews reveal both the current state of AI adoption and the perceived opportunities and challenges it presents. While AI is recognized for its significant potential to enhance decision-making, productivity, and competitive advantage, its integration within SMEs still needs to be discovered. The primary barrier to adoption seems to be a lack of understanding and trust in AI technologies, alongside the high initial investment required for implementation and training.

The enthusiasm for AI's capabilities in improving international market analysis, entry strategy formulation, and overall strategic decision-making is tempered by concerns over the readiness of SMEs to embrace such technologies. The interviews highlight a desire to leverage AI to gain insights into foreign markets, optimize logistics, and reduce risks associated with poor strategic choices. However, more knowledge and trust should be gained regarding AI's effectiveness and application.

This discussion emphasizes the need to bridge the knowledge gap and increase SMEs' trust in AI technologies. Additionally, the study highlights how AI may help SMEs compete on an even playing field with larger rivals by providing affordable, flexible, and long-lasting business solutions. As such, it becomes crucial for policymakers, educational institutions, and industry leaders to collaborate in facilitating SMEs' transition into the digital era, thereby ensuring their competitive stance in the global marketplace. This paper contributes significantly to the ongoing discourse on AI and international business, emphasizing the urgent need for comprehensive understanding, strategic implementation, and supportive frameworks to harness AI's full potential in enhancing the global competitiveness of SMEs.

Research limitations. While this study provides new insights about AI integration into ISD processes, it is important to acknowledge several limitations. First, sampling limits the representativeness of the findings to this specific market, thereby limiting their generalizability. Second, the dynamics within the industry may be partially represented by the focus on manufacturing SMEs. Therefore, future research could explore the impact of AI integration across different sectors and geographical locations. In addition, the implications of AI integration can differ depending on the context and organizational settings. Thus, future research could examine how contextual factors such as sector-specific regulations, market dynamics, and technological infrastructures affect AI's integration. Lastly, while our study briefly touched on

managers' perceptions of AI, a deeper exploration of managers' attitudes, behaviors, and decision-making strategies towards AI adoption is needed. Future research could focus on the managerial competencies and skills required for the effective use of AI technologies in international decision-making processes, as well as the organizational factors that influence managers' attitudes toward integrating AI.

Managerial implications. *The managerial implications that emerge from our findings can serve as a signal to internationally operated SMEs about the value of AI technologies. By understanding the process of AI adoption and its impact on international strategic decisions, firms can align international strategies and optimize operations, respectively. In addition, the findings may have implications for policymakers regarding support for SMEs in integrating AI technologies.*

Originality of the paper. *This study stands out for its focus on AI adoption in international strategy-making decisions, a relatively underexplored topic in the existing literature. Through a case study approach focusing on SMEs operating internationally, the study sheds light on the opportunities, challenges, and implications of AI integration. Emerging findings reveal the role of AI use from different perspectives within ISD processes, such as market selection, entry mode, partner selection, customer engagement, market performance, logistics, and risk management, providing insights that can inform future practices and strategies in these areas.*

Track 4
Management Case Studies

A Public Service Logic perspective applied to health and social welfare services provided to the elderly: the case of the VIII Municipality of Rome

MAGDA TOUTI¹ FABIOLA SFODERA² LUCA DEZI³

Abstract

With the increase of the elderly population, it is necessary to ensure effective and efficient delivery of health and welfare services to this group of people and to be able to meet their requirements. In this scenario, Public Administration plays a key role in providing support and helping to reduce the burden on the hospitals. By adopting a Public Service Logic perspective on a single case study, the aim of this research is to understand how the integration of resources occurs and to identify the key areas of value creation and where improvements are needed. In the preliminary results, an initial mapping of processes is presented, which provides an understanding of what services are provided, how they are accessed, how they are delivered and who are the key players in this process. This work has significant implications, both theoretical and managerial.

Key words: *Public Administration; Public Service Logic; Elderly population; service management; Public Service Ecosystem*

Framing of the research. *Elderly population, in accordance with the definitions of the World Health Organization (WHO), indicates individuals aged 65 years or older.*

Italy's population has a median age of 48.4 years, the oldest in Europe in 2023. Italy ranks second in the world, after Japan, in terms of elderly population (OECD, 2023)

According to the 2023 Annual Report of the National Statistics Institute (Istat), which provides an overview of the demographic, economic and social situation in Italy, the resident population of Italy on 1 January 2023 will be 58.851 million. The population over 65 years of age amounts to 14.177 million individuals and constitutes 24.1 per cent of the total population. The old age index, which measures the number of people aged 65 and over for every 100 young people aged 0-14, has increased from 187.6% in 2021 to 193.1% in 2022, in line with the general population trend.

The population over sixty-five is expected to reach 34.5% of the Italian population in 2050 (ISTAT). With an ageing population and longer life expectancy, the proportion of dependent elderly people is set to increase (Cochrane et al., 2016), requiring more and more health and social welfare services. In fact, the lengthening of life expectancy poses several challenges for the nation, requiring the active participation of all entities to ensure effective delivery of the required services. According to Brunzini et al. (2022), ageing leads to increased costs for both the Italian National Health System (NHS) and the private citizen. For the National Health System, the difficulties mainly concern direct costs for medical care, rehabilitation treatment and hospitalisation, while the citizen is burdened by the costs of prolonged care by caregivers and, in some cases, placement in care facilities (Brunzini et al., 2022). Although the allocation of healthcare resources varies considerably between different Western countries, according to Petrelli et al. (2010), overall, healthcare resources are allocated based on the population's actual need, which is closely linked to their health. In Italy, since the 1990s, the National Health Service has been reformed with the aim of providing equal health care for all, financed through general taxation. Over the years, to facilitate its management, more responsibility was attributed to regional health authorities (Petrelli et al., 2010). As a result, multiple governance models have emerged, with differences in the composition of public and private providers, the number and size of local health units and the autonomy of public hospitals. Since 2000, the regions have also been coordinating, planning, and monitoring social services and, to avoid significant differences in the services provided, the 2001 constitutional reform defined the basic principles and services to be provided in all regions, including health and social welfare services (Cepparulo & Giuriato, 2022). Among the interventions implemented, the "health" ministerial decree of 2007 introduced the Single Point of Access in Italy. The

³ Sapienza University of Roma
e-mail: luca.dezi@uniroma1.it

Single Point of Access is a structure designed to simplify access to the system for citizens through the integration of health and social welfare activities in a broad sense. It is responsible for the reception of requests for assistance, followed by an initial assessment of the need to propose to the citizen appropriate services with respect to his or her needs and the activation of the relevant services (Notarnicola et al., 2015). Nevertheless, although these systems were created with the intention of providing public services with universal coverage, increasing financial constraints and social pressures are leading to a change in the delivery of these services. Indeed, to date, private and non-profit organisations, together with families, are increasingly involved in the planning and delivery of social care services (Longo et al., 2015). To address these challenges, it is necessary to provide sufficient health and welfare services, promote a healthy lifestyle and create a social and physical environment that encourages active ageing. Within this context, public administration (PA) plays a key role in ensuring the provision of effective, efficient, and quality services. This study focuses on the health and social welfare services provided to the elderly by the Municipality VIII of Rome where by health and welfare services we refer to: “the professions that support health personnel in the administration of therapies and in the surveillance and protection of hygiene and public health safety; they carry out physical and manual assistance by performing, within the scope of their competences, prevention, treatment, rehabilitation and functional recovery; they carry out assistance interventions aimed at satisfying the primary needs of patients; they take care of the psychological, motor, recreational and health development of children” (ISTAT). The aim of this study is to identify the actors involved and the key areas of value creation and understand how the integration of resources occurs adopting a Public Service Logic (PSL) perspective (Osborne, 2013).

In the management literature, scholars have highlighted the potential of Service Dominant Logic (SD-L) in promoting the development of more effective services in the public sector (Westrup, 2018) and have proposed a new stream of research called PSDL (Public Service Dominant Logic) or PSL (Public Service Logic) (Ojasalo & Kauppinen, 2024). Over the years, SD-L (Vargo and Lusch 2004, 2008) has been widely applied in the disciplines of management and marketing as a theoretical basis for understanding market phenomena, sectors (Vargo & Lush, 2017) and services (Maglio and Spohrer, 2008). According to this perspective, value is uniquely determined by the customer or user (Vargo & Lusch, 2004) and the role of the company is to offer value propositions. In this reciprocal relationship, producers use their knowledge and skills in production, while customers apply them in the use of the product or service, the “value in use”, and in its evaluation based on context as well as previous experience, the “value in context” (Osborne, 2018). According to this perspective, public services should be evaluated by their ability to facilitate the creation of value in the lives of public service users and other stakeholders (Osborne et al., 2021). This approach incorporates the principles of Service Dominant Logic and is built on four premises (Osborne et al., 2013):

1. Both citizen and user are essential stakeholders in public policy and public service delivery processes, and their engagement in these processes adds value to both.
2. A public service-dominated marketing approach is essential for: transforming the strategic intent of a public service into a service promise or offering; defining the expectations of service users and employees; and providing a solid framework for developing trust in public service delivery.
3. Co-production of the service is an important element of public service delivery and design, placing the experiences and knowledge of the service user at the centre of effective public service design and delivery.
4. A dominant approach to public service management and operations is necessary to ensure efficient and effective public services and to deliver on promises.

Recently, Ojasalo & Kauppinen (2024) proposed different levels of the public service ecosystem. In their framework, the emphasis and interpretation of public value is defined by elected representatives, who belong to or are authorised by the local and regional, national, and international levels (Ojasalo & Kauppinen, 2024):

1. **Citizen level:** The term, citizen level, refers to individual citizens of a public service ecosystem, who are consumers and users of public services. The difference is that while consumers use public services by paying for them directly or through taxes or other means of public financing, users, who may or may not pay for the use of services, are those who actively benefit from them. Public value is the ratio of benefits to sacrifices, which is perceived and defined individually by the citizen. The emphasis is on the individual value of the users of the service provided by the public organisation.
2. **Organisational level:** the integration of resources within an organisation that produces a public service. It can also include digital platform service providers and communities.
3. **Local and regional level:** the integration of resources and their orchestration at the regional level. It is often realised or strongly influenced by the local regional government and its collaborative arrangements. Actors in orchestration typically include, but are not necessarily limited to, organisations or individuals responsible for policy and governance in cities, municipalities, and regions.
4. **National level:** the integration of resources and their orchestration at the national level. It is often made or strongly influenced by the national government.
5. **International level:** the integration of resources and their orchestration that occur in collaboration between nations.

In public service ecosystems, a comprehensive view is undertaken encompassing all individuals, technologies and institutions involved in the creation and delivery of value generated through the public system and adjacent private stakeholders' (Petrescu, 2019).

Purpose of the paper. By identifying and analysing the services provided to the elderly, the objective of this study is to identify the actors involved and the key areas of value creation and understand how the integration of resources occurs through the lens of Public Service Logic perspective. To achieve this objective, we define the following research questions:

RQ1: What are the areas of value creation in local services provided to the elderly in the Public Service Logic perspective?

RQ2: Who are the actors involved and how do they integrate with each other?

The study is developed in two phases. The first is mapping the services offered by the Third Age Area of Municipality VIII of Rome. The second phase consists of interviews with the ecosystem actors involved to understand their functions, roles, tasks, and modes of interaction in the production and service delivery process.

Methodology. To achieve the research objective, this study employs a single case study approach (Hunziker & Blankenagel, 2024). Case studies can be defined as research investigations that examine contemporary phenomena within their real-life context and support researchers in addressing “questions about the how or why of a set of events over which the researcher has little or no control” (Yin, 1994). Accordingly, the case study allows for a holistic representation of the unit of analysis in its environmental context containing all relevant aspects, elements, and relationships. It is a valid research design as it enables researchers to understand developments, processes and cause-and-effect relationships in a particular business and social context, while allowing them to approach real-life situations and directly test perspectives and viewpoints on the phenomena under observation (Hunziker & Blankenagel, 2024). The protocol for data collection and analysis is organized into the following sequential steps.

a) Case selection

The registered population of Rome as of 31 December 2022 is 2,813,544. The phenomenon of population ageing continues to increase Rome's average age, and, over the last decade, it has increased by 2 years, from 44.6 years in 2013 to 46.6 years in 2022. Rome is distributed into fifteen municipalities, each with its own characteristics in terms of territorial extension and population. The most populous municipality is the municipality VII, with 311,500 inhabitants, while the least populous is the municipality VIII with 128,417 inhabitants. The latter will be examined in this study as it is interesting to note that, although it is the least populous municipality, it is also one of the “oldest” (along with municipalities I, II and XV). According to the data provided by the official website of the city of Rome, the municipality VIII has an old age index of 233.8. In other words, for every 100 individuals aged between 0 and 14, there are approximately 233.8 people aged 65 and over. The importance of effective and efficient management of services for the elderly in such a context is evident.

Figure 1: Map of the municipalities in Rome

Source: Official City of Rome website

b) Data collection

In accordance with Yin's (2004) prescriptions, data on the case were collected from various sources, both online and offline:

1. Secondary sources: mapping by relevant data and information on the phenomenon under investigation. These sources included the City of Rome website, academic articles, industry reports, including national, regional and municipal laws, internal memos and regulations.
2. Interviews with the responsible personnel: semi-structured interviews with staff's manager and managers of the Third Age Area⁴ of Municipality VIII were conducted to obtain an in-depth understanding of the organisational structure implemented for the delivery of health and social care services to the elderly.

⁴ The Third Age Area is the department within the Municipality VIII in charge of managing services for the elderly. The office is responsible for the provision of home services and financial support and is responsible both for the activation and monitoring of services.

c) **Data analysis**

To construct the case study, the researchers first conducted process mapping. At this stage, the aim is to define Municipality VIII's organizational structure by identifying which services are provided in the flow of activities and decisions within a workflow related to delivering public services per the principles of the Public Service Logic (Bowles & Gardiner, 2018). Process mapping is valuable for visualizing and improving service processes (McLaughlin et al., 2014).

Results. The research is still in progress therefore the first results are described below. Semi-structured interviews with the staff in charge of the Third Age area and the analysis of secondary sources revealed that the health and social welfare assistance in Rome's Municipality VIII offers five typologies of services, of which a brief description is given below with the aim of understanding the process through which the elderly person, or a member of his or her family, becomes acquainted with the services of the municipality until the moment the service is provided.

Protected discharge service

The protected discharge service is an integrated social home care service activated by the hospital to provide home care for the elderly after hospital discharge. The service is activated immediately after discharge from hospital and lasts 60 days. The team providing this service consists of health workers, for medical and nursing care, and an operator from one of the cooperatives accredited by the municipality who provides support for daily activities (e.g. personal care, hygiene, dressing, small errands, going to the doctor, preparing meals, etc.). A maximum of 7, 30 hours per week can be provided, which are distributed according to the person's needs.

S.A.I.S.A.

S.A.I.S.A is a service that lasts forever from the moment it is activated. This service, similar to the previous one, that focuses on maintaining and recovering the elderly person's autonomy and self-sufficiency. The access requirements are:

- women over the age of 60 and men over the age of 65.
- be in possession of Civil Disability,
- have a severe disability, Law 104/1992⁵, Article 3 paragraph 3.

Specifically, it is a service that provides support for personal care, both at home and elsewhere, help in carrying out activities of daily living, socialisation activities, development and support of personal and social autonomy.

Severe disability

This service is an aid for the elderly and for people with disabilities. It is aimed at the entire disability sector from 0 to 1,000. the contribution is designed for elderly persons who are in one of the conditions expressly provided by the ministerial decree. The requirements are:

1. To be recognised under Law 104/1992, art. 3.
2. Benefit from an attendance allowance.

The service is available under three forms:

- Direct: direct home care through cooperatives
- Indirect: family assistance refund
- Caregiver support

The allowance for direct assistance and caregiver support ranges from a minimum of EUR 400 to a maximum of EUR 700, while indirect assistance ranges from a minimum of EUR 500 to a maximum of EUR 800. The variability depends on the ISEE (Equivalent Economic Situation Indicator) and on whether the user uses other services (e.g. home care).

Alzheimer's day care centre

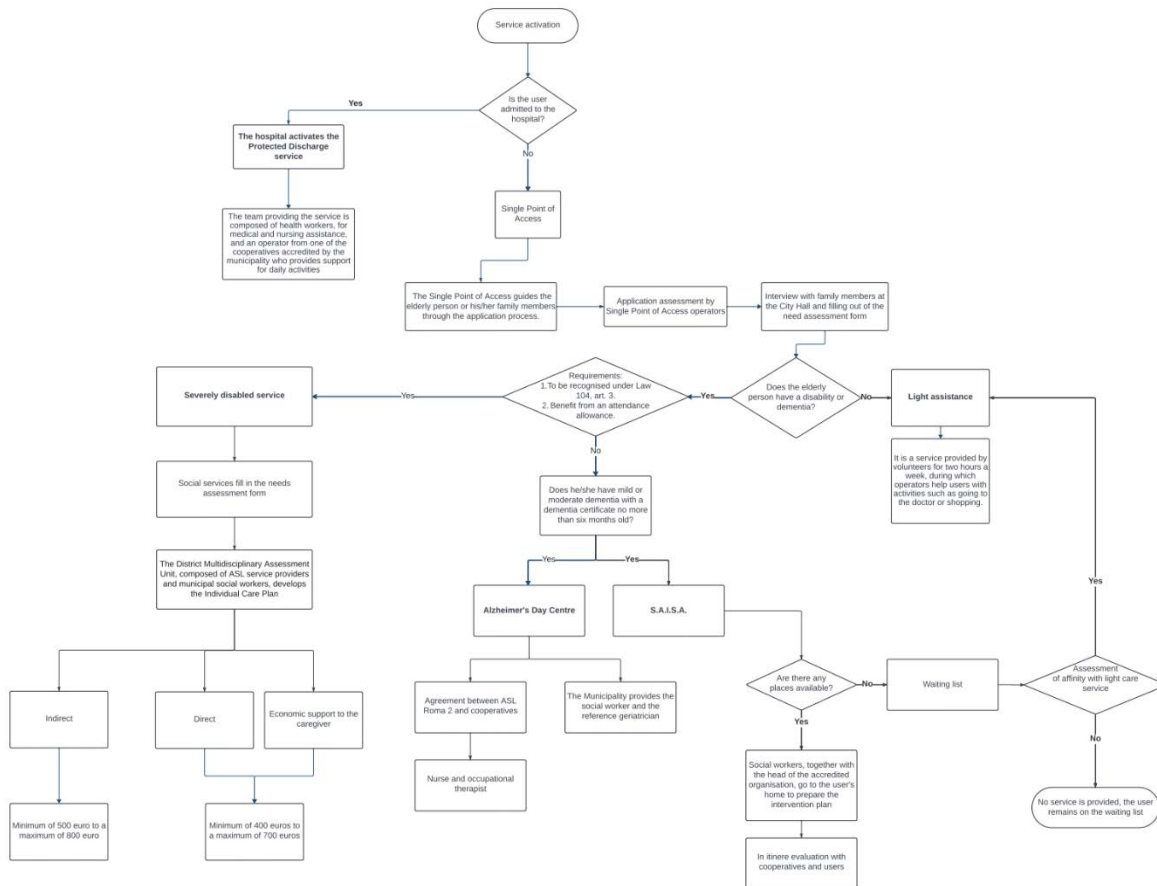

The Alzheimer's Day Centre is a centre for people with Alzheimer's and other mild or moderate dementias. To qualify for admission to the centre, the person must have a dementia certificate that is no more than six months old. The centre accommodates nineteen users from the municipality and is attended 2 or 3 times a week, from morning to afternoon, for 8 hours a day. A transport and meal service are provided for those who request it. Various professional figures are involved: psychologists, professional educators, physiotherapists, occupational therapists, nurses, OS. The centre is attended for as long as the person is able to benefit from the proposed activities, mainly those aimed at delaying the progression of the disease and exercising memory. Various workshops are also carried out (handicrafts, music, etc.), geared towards exercising the person's cognitive functions and his or her orientation in time and space (e.g. carrying out themed activities during Christmas or organising the centre's spaces in a specific way).

Light assistance

This is a service provided by volunteers for two hours a week, during which operators help users with activities such as going to the doctor or shopping. This service is useful because it enables to monitor the health conditions of that segment of the elderly with greater autonomy and self-sufficiency.

⁵ Law 104/1992 is the reference law enacted by the Italian Parliament for individuals with "a physical, psychic or sensory impairment, stabilised or progressive, which causes learning, relational or integration difficulties".

Figure 2: Process map of health and social welfare services provided by the VIII municipality of Rome

Each of the services offered has different access requirements and forms of provision. For each service, the process starts from the Single Point of Access. Specifically, Single Point of Access guides the elderly person or its family members to submit the application. Subsequently, the application is assessed by the operators, and an interview with the family members is held at the city hall. Once the documentation regarding the application and requirements is received, a home visit is conducted. During this visit, a “needs assessment form” is used to provide an overview of the elderly person's situation in terms of level of autonomy and self-sufficiency (e.g. if they are able to dress themselves), family situation (e.g. if they live alone or not), financial situation and architectural barriers. An evaluation form is completed and used to decide whether and what type of service to activate and how many hours of assistance are needed. Finally, a project is drawn up, the 'intervention plan', containing the objectives, interventions, times, days and costs.

The results are expected to emphasise the significant role of the Single Point of Access (PUA) as a crucial distribution hub for the various service areas. From the process map it emerges that there is no upstream control, but several ongoing controls whose modalities are not clear. Indeed, the services are also provided by third parties - cooperative operators and volunteers selected by them - without there being rigorous controls to ensure quality. This is a relevant aspect as the volunteer is in close contact with the elderly person, i.e. the most important area of value creation. However, the function is delegated to a volunteer selected by a provider, meaning that there is a significant economic investment on a service that is delegated to the ethics of the provider who is free to select volunteers without strict constraints. In terms of theoretical implications, the findings are expected to emphasise the need to adopt an ecosystem approach within public services that considers different levels of analysis (citizen level, organisational level, local and regional level, national level, international level) by developing the concept of service ecosystems in the Public Service Logic Theory. Furthermore, the article addresses the call for more studies on value co-creation in service ecosystems and the role of public service providers as value facilitators (Osborne 2018).

Moreover, the services can be distinguished into (van der brug et al., 2019): on-demand services, in which customers have access to a service immediately when experiencing a need anywhere and anytime, and on-request services, in which it is not certain that the service requested will be immediately available. Therefore, in this case, the flow is activated when there is a request, but the service can also be delivered at a later time. In this study, the services provided by the municipality VIII of Rome are on-request. From a management point of view, the on-demand modality allows for greater programmability of services as it does not require immediate access to the service to anyone who requests it. However, the presence of approximately 250 people on the waiting list indicates a high degree of inefficiency in public service delivery.

Research limitations. *The main limitations of this study are related to the difficulty of gathering information in a context that requires access to data from different sources, i.e. local authorities and cooperatives working with them, health institutions and social welfare organisations. The Italian Health Service perspective can influence the number and type of actors in the ecosystem based on normative provisions. Furthermore, the complexity of the ecosystem and the multiplicity of actors involved make it difficult to accurately design all the stages without having interacted with all the actors, leading to additional details that may be relevant not being considered in the process. A further limitation concerns the use of the case study and the generalisability of its results to other contexts, especially those in which the public service delivery system is very different from the Italian context.*

Managerial implications. *The study has important implications for both public management theory, public policy, and the management and delivery of public services. The actors affected are numerous and include policy makers, health professionals, managers, and public and private organisations (both local and national) involved in the management and delivery of services for older people.*

Originality of the paper. *The originality of the study lies in the adoption of the Public Service Logic and its integration with process mapping to identify areas of value creation in the public service delivery process and improve its efficiency and effectiveness to meet the growing challenge of an ageing population.*

Interpreting long-lasting corporate crises according to stakeholders' perspective: evidence from the ILVA experience

SILVIA COSIMATO¹

Abstract

The aim of the short paper is to provide a holistic overview of corporate crises by investigating how different stakeholders and interests are impacted by a corporate crisis over time. To offer a multi-stakeholder and longitudinal analysis of corporate crises, an exploratory approach based on extreme case study is adopted. The research examines the case of an Italian company whose crisis extended over a long period and presented multiple dilemmas to decision-makers: the ILVA. Using a content analysis, we examine how corporate communication, newspapers, and press releases have approached the ILVA crisis over time. The results show how strategic priorities have been established and renegotiated over time, as new issues have emerged, demonstrating the difficult to achieve a balance among different stakes, especially in the face of economic pressures and regulatory challenges, and that environmental and health issues should be considered together with the economic conditions.

Keywords crisis management, stakeholder, sustainability, case study

Framing of the research. Crises are complex events stemming from long-term disruptive processes that challenge corporate legitimacy and threaten firm performance, involving several different stakeholders (O'Reilly et al., 2015; Williams et al., 2017; Li et al., 2023). These disruptive and often unexpected events tend to challenge companies' legitimacy, creating uncertainty and a certain incongruence between the desired corporate image and the image that stakeholders perceive (Seeger et al., 2003; Sellnow and Ulmer, 2003). Drawing upon the extant literature, corporate crises have been defined as a pathological situation in a company's life that endangers its survival (Sciarelli, 2011), or as "the extreme consequence of the increasing decline of corporate profitability" (Abatecola, 2012, p.862). However, it is worth noting that most of the research focuses on either the causes of the crisis or the most effective coping strategies, primarily from an economic or financial point of view. Moreover, research primarily focuses on the definition and the analysis of corporate crisis antecedents, highlighting that anticipating a corporate crisis is not an easy target to hit, due to multiple and often intertwined macro-environmental, industrial, and/or firm-specific factors (Ou and Wong, 2021). Several variables (e.g., the nature of the antecedent or triggering event, the involved stakeholders, etc.) contribute to defining the way scholars and practitioners approach these crises (Heller and Darling, 2011), even though they tend to consider information asymmetries between a firm and its stakeholders one of the most common threads in existing studies on the topic (OuYang et al., 2017).

Coombs (1999) defines crisis management as "a process of moving from the unknown to the known through information gathering and processing" (p.127). This definition highlights the information- and knowledge-intensive nature of crisis management; thus, to enact efficient and effective processes, it needs the right information to inform corrective actions (Coombs, 2010). Information is essential for supporting managers in making sense of a crisis, focusing on its causes and possible solutions. Moreover, to manage critical situations, efficiency (which comes from the ability to maximize the relation between operating and liquidation value, avoiding unnecessary value destruction and minimizing the related costs) and equity (which emerges when the different interests and priorities are respected) are essential to make a company able to navigate the crisis and survive (Franceschi and Tedeschi, 2014). It follows that one of the main challenges of the extant research is understanding how to approach and fix corporate crises, mainly through crisis management mechanisms, essential to make companies able to protect their and their stakeholders' interests making their value creation and sharing processes sustainable over time (Ponis and Koronis, 2012). Being able to prevent or "manage a corporate crisis is pivotal to a corporation's long-term success" (Kim and Atkinson, 2014 pages 662).

Overall, existing studies focus on the financial and economic aspects of corporate crises and the tools to fix them. This is unfortunate as they offer an incomplete portrait of this complex phenomenon whose implications extend beyond the economic or financial domain and involve environmental or social issues. This is a significant limitation, especially considering recent theories that emphasize that the firm is a place where stakeholders' heterogeneous align one another. For instance, crises involving large companies display that their negative consequences not only impact the shareholders, creditors, or the employees, but also extend to the supply chain and the local communities where corporate facilities are

¹ University of Napoli Federico II
e-mail: silvia.cosimato@unina.it

located (Janssen et al., 2015). In other words, the economic consequences of the crisis of a large company go far beyond the estimated losses in accounting documents and restructuring plans. The consideration of such effects often induces governments to intervene and assist companies in crisis not only to revive them and restore economic and financial balance but also their competitiveness (Köhler, 2022). Such interventions are justified by collective interests — or the relevance of the sector involved, the impact on employment levels, including those linked to the supply chain, and the well-being of local communities—that overlap with those of the shareholders of the company in crisis. In such circumstances, State intervention seems to represent a solution reconciling economic and social sustainability. However, some cases of large Italian companies in crisis suggest that such intervention has not always produced benefits for everyone, and in any case, the hoped-for results. In particular, stories of public intervention in companies in crisis that have lasted for decades testify to the difficulties of managing a successful restructuring process. In the Italian context, experiences such as those of Alitalia or ILVA indicate the difficulty of finding a balance between interests (economic, social, and environmental) in different time horizons, the short, medium, and long term.

The above considerations suggest a holistic investigation of corporate crises with the considerations of how tensions among different stakeholders and stakes are solved over time (Sun, 2023). Following Coombs (1999), we highlight the information- and knowledge-intensive nature of crisis management, and we contend that to enact efficient and effective processes, gaining the right information and, therefore, the right knowledge at the right time, place, is key to solving a crisis (Coombs, 2010; Sciarelli, 2011). More specifically, we highlight that making sense of corporate crisis' causes, and to take a step forward in its resolution it is essential to consider their potential or real impact on the involved actors. In other words, information is essential to develop and enact specific recovery strategies, and related action plans, such as recovery and continuity plans to restore the conditions of business, economic, and financial equilibrium (Sahebjammia et al., 2015; Tron et al., 2018). These plans represent some of the possible operational tools that a company can use for managing a corporate crisis, and in doing so avoiding failure. Relatedly, communicating the required changes is an inherent component of a crisis management plan.

Purpose of the paper. This work has been conceived as a first step of a major research on the corporate crises that have and are still affecting Italian privatized large companies inspired and directed by the Professor Sciarelli. Thus, he inspired the authors in their contribution to better understanding corporate crises, and the way they are approached, investigating how different stakeholders and stakes are impacted by a corporate crisis over time. To provide a multi-stakeholder and longitudinal analysis of corporate crises, we investigate an Italian firm whose crisis has extended over a long timeline and has presented multiple dilemmas to decision-makers. To achieve this goal, it has been traced how the corporate crisis has been dealt with over time. More specifically, by looking into how corporate communication, newspapers, and press releases have approached it over time. In this way, we aim to offer a better understanding of the way strategic priorities have been set and renegotiated over time, as new issues have emerged and come to play, offering, at the same time, a more comprehensive and longitudinal interpretation of corporate crises and its main challenges from a stakeholder lens. In doing so, we intend to provide multiple contributions. First, we intend to expand the consideration of implications of corporate crises beyond the economic or financial realm and disentangle social and environmental implications over different time horizons. Second and relatedly, we contextualize social and environmental issues during a firm's pathological conditions. In such circumstances, the balance among competing stakes is more difficult to achieve. Our contribution unravels these tensions and may offer important managerial, and policy implications.

Methodology

Research approach

This study is based on an exploratory approach aimed at contributing to the research on corporate crisis management and the way recently privatized Italian corporations have approached crises over time. A qualitative analysis has been conducted performing a case study analysis (Yin, 2003) to offer an in-depth description of the phenomenon under investigation and pave the way for further research. The case study approach can be considered a suitable research strategy as it sheds light on various facets of the phenomenon under investigation, helping to explore a complex phenomenon when hypotheses are difficult to define before collecting research data. In other words, a case study helps to answer “how” and “why” questions (George and Bennett, 2005). As reported by George and Bennett, (2005) a case study helps “to explore a significant phenomenon under rare, unique or extreme circumstances” (p.18).

The analysis fits the extreme case study method, which is particularly fruitful when the research goal is to gather insights about a specific phenomenon by learning from a rare or unusual positive/negative example. This method is used when “the objective is to achieve the greatest possible amount of information on a given problem or phenomenon, [in such circumstances] a representative case or a random sample may not be the most appropriate strategy. This is because the typical or average case is often not the richest in information. Atypical or extreme cases often reveal more information” (Flyvbjerg, 2006, p.222). Drawing on these considerations, ILVA represents an extreme case study because it makes possible to learn from an unusual negative example of how a big Italian corporation handled a long-lasting corporate crisis after the privatization, which affected not only the corporate viability but also its harmful impact on both the local environment and society.

Research setting

ILVA is a long-lasting steel company set in Taranto, whose corporate history started, in 1905 in Genoa when Italy's leading steel companies created the ILVA Consortium in 1911. In 1961, the company merged with Cornigliano Steelworks creating Italsider. In 1965, the steel plant in Taranto started operations as Europe's largest steel producer. Still, the entire industry experienced a decline from 1975 to 1983. In 1995, the Riva Group acquired the Taranto plant, reinstating

the ILVA name. The long history of this primary Italian company passed through four main events a) the establishment of the production facility with direct public management, b) the privatization of ILVA's management, c) temporary receivership, d) the intervention of the multinational ArcelorMittal. Over the years, the ILVA crisis became even more severe because it was alleged of negative externalities for the environment (e.g., dioxins and other carcinogenic emissions) and consequently for local community. At the beginning of the second decade of the XXI century, some analyses and reports demonstrated the increased rates of cancer and other chronic diseases among the population living in the city of Taranto. It was in 2014 that the first formal investigations by Italian and European authorities were presented. In the same period, ILVA experienced changes in ownership and management to make the company able to overcome its long-lasting financial, environmental, and social crisis. To sum up, the ILVA case is extreme because it epitomizes the conflict between industrial and economic development and environmental and public health protection. The Taranto plant is a major employer in the region, contributing significantly to Italy's economy. However, the environmental and health costs have sparked a heated debate about the sustainability of such industrial operations and the necessity of stringent regulatory oversight. The Italian government has intervened on several occasions, either to try to clean up the plant or to take it over temporarily to safeguard jobs while attempting to bring the operations in line with environmental and health standards. Public outcry, both locally and internationally, has been vocal, with protests and campaigns demanding a resolution to the health and environmental crisis.

Data collection and analysis

To better understand the way Ilva (e.g., crisis management strategies, recovery strategies, recovery, and continuity plans, etc.) approached corporate crisis we performed a content analysis (Krippendorff, 2009; Kohlbacher, 2006) to test if and how ILVA communicated to its stakeholders the mechanisms implemented to face corporate crises. Indeed, content analysis “is a research technique for the objective, systematic, and quantitative description of the manifest content of communication” (Berelson, 1954, p. 489). This method is particularly suitable to address the research topic under investigation because it “involves an inductive exploration of the data to identify recurring themes, patterns, or concepts and then describing and interpreting those categories” (Nassaji, 2015, p. 130). The analysis was conducted on 150 documents (reports, news, etc.), selected according to a convenience sampling strategy (Etikan et al., 2016), a strategy implemented for collecting data when a sampling frame is not easy to define, allowing the selection of the sample units according to their accessibility (Bryman, 2012). To this end, the following selection criteria were set, accessibility, source (or authorship), and topic relevance and consonance with the main purpose of the study. Thus, documents dealing with the case company crisis and the related recovery strategies and plans published by the company itself and/or other stakeholders (government, media, analysts, citizens, etc.) over the last 12 years were selected to investigate stakeholders' perception of the way it managed the crisis with a special focus on the way it used the governmental recovery measure. The timeframe was set after the investigation of the ILVA history; thus, 2012 represents a critical milestone for the case company because this year the first forensic examinations were presented, and the national authorities seized the Taranto plant.

Documents were selected performing an open-ended iterative search process (Finfgeld-Connett and Johnson, 2013), based on ongoing searching, reading, and refining of the research problem. This process was conducted by 1) searching, 2) sorting, 3) selecting, 4) acquiring, 5) reading, 6) identifying, and 7) refining documents.

The first step (searching) was conducted by checking the title and the occurrence in the title and executive summary of some keywords that represent the topic under investigation, 1) corporate crises, 2) recovery, and 3) state intervention. In this way, it was possible to sort and select documents as well as to make them comparable. Moreover, after the first screening, these documents were organized to be used for the content analysis (Tab.1).

Table 1: Sampling criteria

Sampling criteria	
Topics	Corporate crises, recovery, state intervention
Data sources	Media, institutional, and corporate online databases
Authorship	case company, media, NGOs, institutions, citizens
Publication date	from 2012 to 2024
Language	Italian

Source: Authors' elaboration

This process led to sorting 150 documents, which were comparable and met the aforementioned criteria. These documents were written in Italian, accessible online, and dealt with the ILVA crisis. The analysis was conducted in Italian, but the results were translated into English. After this iterative process, the reports were analyzed according to some main elements dealing with crisis management derived from the literature. The quality of the analysis was ensured through 1) the construct validity, related to the achievement of suitable operational measures for analyzing concepts related to corporate crises, and 2) the internal validity, related to the appropriateness of the content analysis items (or themes), by triangulating different data sources, such as other reports, online news, webinars, etc. (Mason and Bramble,

1989). The content analysis was based on three main phases: 1) preparation, 2) organization, and 3) reporting (Elo and Kyngas, 2008). During the preparation phase, two researchers collected data (documents and news related to the ILVA crisis over time publicly available on websites or by requesting download permission, according to the selected sample criteria (see Tab.1). A dictionary containing the keywords derived from the extant literature was developed and used for the analysis. It consisted of a list of words organized into two main coding categories: 1) Corporate crisis, and 2) State intervention. Into this list, singulars and plurals were grouped, articles, auxiliaries, and prepositions were dropped out, while keywords' consistency was ensured using an English dictionary of synonyms and antonyms.

The organization phase consisted of a codebook (made up of categories, and keywords), used for organizing the results obtained. Two researchers independently checked the codebook for consistency. The content analysis supported the interpretation of the quantitative count of the coded texts descriptively. In doing so, some content units (or "observations" in inferential statistics) were defined. Each sentence reported in the analyzed documents was considered a content unit, which set the limits on the information to be considered in the description" (Krippendorff, 2009, p. 101), while the word was set as a unit of analysis. Finally, the reporting phase consisted of the organization of the units of analysis (words) into the coding categories defined before starting the analysis. Words' detection and counting were conducted using Maxqda software. A word-count matrix was created to organize results, according to some specific categories defined according to the authorship and/or the subject who published information or talked about a specific issue related to the ILVA long-lasting crisis. This contributed to making results easily comparable.

Table 2: Coding categories and keywords for the content analysis

Coding categories	Keywords
Corporate crisis	citizens, compulsory administration, crisis management, data breach, decline, earning crisis, disclosure, environment, environmental impact, ESG, financial exposure, information asymmetries, insolvency, failure, law, liquidity crisis, misconducts, moral hazard, natural disaster, optimization, people, privacy scandal, pollution, profitability crisis, public health, quality, restructuring, recovering, society, risk, sales scandals, social impact, sustainability,
State intervention	Action plan, compensation, criticalities, direct intervention, financing program, government, indirect intervention, incentives, institutions, local development, job protection, monopoly, nationalization, national development, national economy, privatization, public-private partnership, planned economy, policies, regulation, protection, public resources, state intervention, state participation.

Source: authors' elaboration.

Results. While the empirical analysis is still ongoing, in this section we present some interesting preliminary results. More specifically, our findings refer from the content analysis on the 45 documents out of the 150 (see table 3) tables. Thus, starting from the original 60 keywords associated with the 2 coding categories, and due to their adherence to the selection criteria, just 127 keywords were detected. Some keywords were not retrieved into the analyzed documents, and those with less than 40 occurrences were not considered. Therefore, 5 keywords did not occur (ESG, information asymmetries, optimization, cooperation, nationalization) and 12 did not exceed 40 occurrences (crisis management, data breach, financial exposure, liquidity crisis, misconducts, moral hazard, privacy scandal, profitability crisis, quality, sales scandals, monopoly, public-private partnership, planned economy) (Tab. 3).

Table 3: Keywords with no occurrences for each kind of analyzed document

Case Company	Media	NGOs	Institutions	Citizens
	ESG	ESG	ESG	ESG
information asymmetries	information asymmetries	information asymmetries	information asymmetries	information asymmetries
	Optimization	Optimization		optimization
cooperation		Cooperation		cooperation
nationalization	Nationalization	Nationalization	nationalization	nationalization

Source: Authors' elaboration.

Our results indicate that the most recurrent keywords in the documents (with more than 100 occurrences) were compulsory administration (108), risk (111), natural disaster (124), environment (221), law (155), pollution (188), people (190), sustainability (197), public health (204), environmental impact (211), belonging to the first coding category "Corporate crisis". The most occurrent keywords of the second category named "State intervention" are criticalities (112), indirect intervention (117), state participation (160), public resources (166), national economy (177), direct intervention (187), job protection (197), state intervention (209), privatization (187), protection (159).

The preliminary analysis has been conducted without grouping the achieved results into five different categories, defined according to document authorship (case company, media, NGOs, institutions, citizens). However, the results obtained from the content analysis were further analyzed focusing on the inner meaning of each keyword. It is not

surprising that the most recurrent keywords are environmental impact (211), and environment (221). This is mainly due to the long-lasting environmental impact that ILVA activities have had over time. In fact, when the Taranto plant was created, it was meant to be strategic “for the Italian economy since the industrialization following the Second World War. Unfortunately, in those last decades of the twentieth century, the ecological conscience was almost nonexistent” (Rinaldi, 2018, p.25). Therefore, it took some decades to make public opinion aware of the sustainability-related risks associated with the ILVA steel plant in Taranto, whose levels of pollution started to worry the Italian authorities and the European Union Commission in the first years of the XXI century.

The first condemnation for environmental pollution came in 2005, when the ILVA group, one of the most strategic Italian companies, was recognized guilty of severe environmental pollution dangerous for public health (Supreme Court, 28 September 2005, No. 38936). If the high number of occurrences of the keywords environmental impact, and environment is due to the ILVA unsustainable approach to operations, it is worth noting that this has had and still has negative consequences for both human and animal health (Lai et al., 2019), as the high number of occurrences of the keyword public health points out. To counteract this situation, Italian authorities forced ILVA to comply with the environmental legislation and to fix the socio-economic damages caused by its production activities. In fact, in 2012 an epidemiological appraisal reported the rising number of chronic diseases (especially cancer) among people working at the ILVA plant and in the city of Taranto. Consequently, in the same year (on the 26th of July) a court ordinance stopped the operations of this company, accused of environmental hazard. This led also to a better understanding of the high number of occurrences of the keyword natural disaster (124). However, it is worth noting that the case company did not comply with environmental standards for many years (European Commission 2017). This ordinance caused some tensions between the Italian Judiciary Authority and the Italian Government; thus, “in contrast with the Magistrate’s decision, in October 2012 the Environment Ministry promulgated a decree containing prescriptions with the aim of guaranteeing business continuity, and consequently job protection (which is a keyword occurring 197 times) imposing a compulsory administration” (Lai et al., 2018, p.73). This contributes to better understand the reason why the keywords compulsory administration (104) and state intervention (209) highly occurred. Moreover, it is often associated with the traditional “welfare state”, which since the 1950s has been based on state interventions both in the economic and social spheres (Turco and Leopizzi, 2020). Over time, this intervention has been progressively reduced and rationalized, limiting it to face critical situations, discourage unfair competition, and guarantee products/services essential for both the national economy and people’s wellbeing. This implies that the Italian state tends to act as a “last resort regulator” able to solve critical situations and challenge socio-economic risks (Gouldson and Bebbington, 2007). This contributes to better understating why state intervention is among the most occurrent keywords together with environmental impact, environment, and public health. In fact, when environmental and social risks occur, the state intervene[s] only as a regulator of last resort where issues are of such significance that guarantees are needed or where other forms of regulation fail” (Gouldson and Bebbington 2007, p. 7).

Managerial Implications. Although preliminary, our findings bear important managerial implications. The ILVA experience suggests that a crisis cannot be fixed by only looking at economic or financial figures. ILVA experience shows that the balance among different stakes is difficult to achieve, especially in the face of economic pressures and regulatory challenges, and that environmental and health issues should be considered together with the economic conditions.

Originality of the paper. To the best of our knowledge this is the first attempt to study a corporate crisis looking at how environmental, societal and competitive issues are balanced over time. Our study is also an attempt to investigate sustainability issues and practices in a pathological condition, such as a corporate crisis.

Research limitations. Our work is not free from limitations, which in turn provide opportunity for future research. At this stage, the primary limitation is that our findings refer to an extreme case study, which are not generalizability to other settings. Future research can integrate these findings in two ways. First, by performing additional case studies taking into account different industry and institutional conditions. A further step towards the generalizability of these findings is conducting survey on large sample of crises to investigate the most effective policies, strategies and plans to be implemented to overcome these situations. A second important limitation of our study is that it is based on secondary data only. Future research can address this issue by collecting primary data from the multiple stakeholders involved in and affected by a corporate crisis.

Knowledge sharing and learning: face-to-face and ICTs

LORIS SANTARELLI¹ FRANCESCA MASCIARELLI²

Abstract

In complex work contexts, requiring significant experience, individuals continuously share knowledge to perform their activities effectively. Here, only formal education may have little impact, as opposed to spontaneous forms of learning. This paper explores how different types of learning - contextual, experimental, reflexive, and vicarious learning - occur when individuals perform fieldwork-based activities together. By focusing our investigation on a unique context: Abruzzo, Lazio, and Molise National Park (PNALM), we observe the role of face-to-face and digitally based interactions for knowledge sharing. Qualitative data were collected with interviews and content analysis was used to identify the main themes. First of all, we found that contextual and vicarious learning mostly occurs with face-to-face interactions. Conversely, ITC also proven to be a valuable tool for supporting learning, particularly reflexive learning. Secondly, we demonstrated the fundamental role played by fieldwork-based and office activities in different types of learning. Finally, we discussed how the four typologies of learning impact on explicit and tacit knowledge. In conclusion, we contribute to academic literature on knowledge sharing and learning by identifying underlying mechanisms and tools facilitating these processes.

Key words: Learning, knowledge sharing, knowledge, communication tools, groups.

Framing of the research. Knowledge assumes an important role as a resource providing the fundamental assets for organizations engaged in complex environments (Bosua & Scheepers, 2007; Davenport & Prusak, 1998; Kraus et al., 2021). While the business activities require even more coordination, information exchange, and specific know how, it becomes indispensable for individuals to continuously learn (Edmondson et al., 2007). Organizational literature widely analysed learning and focused on how learning processes take place during different organisation activities, how individuals share their knowledge each other's or with other teams at different levels (Hansen et al., 2005; Lemmetty & Collin, 2020; Nonaka, 1994; Nonaka & Takeuchi, 1995; Pisano, 1996). Research on individual and group learning could deepen our understanding of the factors that drive knowledge sharing, thereby enhancing individual and team learning capabilities, as well as their know-how and skills. In this context, knowledge sharing is the essential means through which individuals can contribute to the increasing effectiveness in performing activities, innovation, competitive advantage and finally the performance of the organizations (Cabrerera et al., 2002; Davenport & Prusak, 1998; Wang & Noe, 2010).

In uncertain and complex work contexts requiring continuous collaboration, trust, and significant knowledge, extant studies provide little insights on individual learning processes taking place while they are working in groups in these fields. Uncertainty refers to challenging conditions such as hard-to-reach locations, shortages of resources, or the absence of enabling technologies (Bosua & Scheepers, 2007; Duncan, 1972; Schulz, 2001). Complexity refers to the requirement of significant experience to make complex decisions or perform complex activities (Duncan, 1972; Vasconcelos & Ramirez, 2011). It therefore becomes increasingly important to understand how, on which occasions, and by what means individuals share their knowledge.

Nonaka and Takeuchi (1994; 1995) identified four typologies of learning according to the level: individual learning, group learning, organizational learning, and inter-organizational learning. We focus on how individuals learn within groups. The process where they, through intuition and interpretation, generate new insights, modify traditional mindset, and develop competencies by experimenting. Starting from the classification, Harvey, Bresman, and Edmondson (2018), in their study focused on team learning and cognitive capabilities, they developed a framework composed by four categories of learning: reflexive, experimental, contextual, and vicarious learning. Accordingly, reflexive learning refers to the activities in which the team analyses and evaluates previous information, experiences, or past actions by which the members become able to increase the efficiency and the quality of their outcomes. To increase their performance, the team develop new ways of doing tasks based on what they have learned (Edmondson, 2002; Harvey, Bresman, & Edmondson, 2018). Reflexive learning occurs while performing internal, exploitation-oriented activities concerning information sharing, analysis, and storing. Usually, it ensures efficiency and performance improvements because teams

² University of Chieti
e-mail: f.masciarelli@unich.it

evaluate past events (Harvey, Bresman, Edmondson, et al., 2018b). Contrary, experimental learning takes place when action precede the cognition (Crossan & Sorrenti, 1997). It occurs when team members develop new knowledge or insights through experimentation or test (Edmondson, 2002). Sequently, the third form of learning is defined contextual learning. It allows teams to learn from external sources relying on the key aspect of the context in which they learn (Bresman, 2010). The last type of learning, according to literature, is vicarious learning. Vicarious learning refers to the possibility to learn from the experience of the others with prior or major experience of who is learning (Bresman, 2010; Myers, 2021). Therefore, learning has been recognized as a process that is both social and collective phenomena (Teece et al., 1997; Teece & Pisano, 1994) because what individuals learn is linked with their social context and reflect what they put it into practice (Brown & Duguid, 2001).

Following Edmondson (1999; 2002), we refer to knowledge as the principal result of learning processes. Accordingly, she studied how it is discovered and applied through learning enabling teams to find solutions that were not previously addressed (Sole & Edmondson, 2002). As widely cited in the literature, knowledge can be classified as tacit and explicit. Tacit knowledge refers to beliefs, mental models and individuals' perspectives that is hard to formalize or share with others (Nonaka, 1994; Polanyi, 1967). Tacit knowledge resides in human brain and cannot be easily captured or managed, but it can be observed through actions. As business environments become increasingly complex and uncertain, there is a growing necessity for a deeper understanding of the role played by tacit knowledge (Kenneth, 2007; Polanyi, 1967). In contrast to the tacit dimension, explicit knowledge can be expressed in words or number and represents a minimal part of all the possible knowledge. Explicit knowledge refers to the knowledge that can be articulated in formal language and can be easily transferred to others (Nonaka & Toyama, 2003; Polanyi, 1967).

In this context, knowledge sharing is the ability to transfer previous experience, information, know how, explicit, and tacit knowledge between individuals (Cummings, 2004; Hansen et al., 2005; Kenneth, 2007). It is a mean by which organizations create and make knowledge available to the others (Christensen, 2007; Cummings, 2004). Individuals share their knowledge through both traditional and ICTs communication tools as they differently convey various types of information and support knowledge sharing. Communication tools such messaging platform, mobile call, e-mail as well as other technologies to collect and share information in real time based on IoT, sensors, and database are implemented to ensure the flow of information needed for complex business environments (Cantù & Corsaro, 2007; Ngah & Jusoff, 2009; Paroutis & Saleh, 2009).

Even though the literature on knowledge sharing increases, the discussions are mainly focused on how it is shared, in terms of best practices and process that consider knowledge as a "stock" to be transferred (Christensen, 2007). While the stock represents what has been learnt, Bontis and others (2002) studied how this stock can evolve over time (Kogut & Zander, 1992; Nonaka, 1994a). It is both important to recognize how this stock develop and how individuals take these new insights (Bontis et al., 2002). With the diffusion of ITCs, these processes have become increasingly effective in acquiring and exchange knowledge (Bennet & Tomblin, 2006; Edmondson et al., 2001; Ruiz-Mercader et al., 2006) because ITCs enhanced the availability of communication channels and facilitated access to information (Bennet & Tomblin, 2006).

Literature provided several insights on the use of ITCs in learning processes. Levitt and March (1988), and Teece (1994) focused on balancing exploration and exploitation to sustain organizational performance. Learning processes can also be influenced by individuals who use the technology (Garfield et al., 2001), the style of management (Aranda et al., 2014), the organizational conditions, and employees' networks and relationships (Grandon Gill, 1995; Harris, 2010; Lave & Wenger, 1991; Wenger, 2008).

Purpose of the paper. While formal education, especially in continuous changing organization environments may be limited, we observe how different forms of learning - contextual, experimental, reflexive, and vicarious learning (Harvey, Bresman, Edmondson, et al., 2018) - occur when individuals are working in highly complex contexts (Burns et al., 2005; Choi et al., 2009; Enos et al., 2003). These conditions clearly elicit the presence of tacit knowledge since it is embedded action and context (Nonaka, 1994). Additionally, to carry out business activities in these contexts, individuals are engaged in a network in which relationships are increasingly supported by both face-to-face interactions and digitally mediated interactions (Razmerita, Kirchner, et al., 2016; Razmerita, Wren, et al., 2016). Depending on their activities, individuals utilize various communication tools, ranging from traditional to technological tools (Aljuwaiber, 2016). Consequently, these options delineate diverse modes of communication, information exchange, and knowledge sharing.

The aim of this paper is to explore how different types of learning occur in organizations characterized by a complex and uncertain environment, where both live and technology-mediated interactions are essential, and there is a strong component of knowledge sharing. Particularly, we aim to unpack learning processes by focusing on facilitators that we identified from the literature and interviews: communication tools and organisation activities, with the scope to understand how learning through practice shape in knowledge. Therefore, our research question which lays the foundations for this paper is:

How do communication tools and activities impact on learning processes? How does learning processes shape knowledge within complex organisations?

Methodology. The research method is based on a single case study (Yin, 2003) developed with primary data collected through documental analysis and open-ended interviews (Oppenheim, 2000). We developed an in-depth case study by analysing internal relationships, learning activities, individual and organizational knowledge, and finally, the role played by communication tools in these processes within PNALM. We settled on this single case study as it provides valuable insights to deeply explore the learning processes during the activities that the organization directly perform within the real-world context. The national park context is an attractive setting in which our phenomenon of interest could be directly

observed since this context provides high visibility of teams and groups behaviour dealing with a dynamic, uncertain, and complex work on the field. More specifically, the work activities, to be carried out, require a deep knowledge of the surrounding natural environment and the species, the capacity to make decisions in a short time, and, above all, a high propensity for trust and teamwork.

These characteristics that actors must cope with, while working in the national park, create a context in which continuous learning, especially through direct experience on the field and from more experienced actors is critical. Additionally, these learning activities are also related to a strong heritage of tacit knowledge. Tacit knowledge is usually hard to express, articulate, or document (Nonaka & Takeuchi, 1995), and, in this context, it takes a leading part in carrying out the activities and must be continuously shared among team members. In addition, this empirical context is also valuable for the presence of a complex technology adoption supporting all the activities and the interactions among individuals forming a network supporting all the internal actors in addressing their purpose.

The particular and challenging environment in which work activities take place, together with the importance of relationships and the use of technologies in diverse types of activities, makes this context ideal to observe how individuals learn within groups and how knowledge sharing processes occur.

Firstly, we conducted the documental analysis to ensure validity by using multiple sources of evidence. This analysis included information and details such as the organization's initiatives and collaboration, the involved actors, their activities, adopted technologies, the organizational structure, their future projects, and events. Secondly, after conducting the documental analysis, we collected primary data with open-ended interviews. The interviews started with general questions about the interviewees' first experience and their career path. The questionnaire was composed of introducing questions, five sections concerning monitoring activities, technology, personal relationships, data sharing, external collaboration, and further questions to conclude the session. To let the insights emerge, we conducted 16 interviews with multiple employees and actors within PNALM belonging to different organization's sectors: direction, scientific sector, communication sector, rangers, and a tech company providing IoT technologies. The first interview lasted 2 hours and the subsequent approximately 1 hour. All the interviews conducted have been recorded, transcribed, and coded in order to identify all the relevant topics and develop the case study.

Thereafter, we applied the content analysis method to analyse the interviews. The pre-coding phase has been carried out starting from the development of a dictionary structured with the most relevant concept found. This phase consisted of a preliminary analysis where we highlighted the most frequent keywords from the interviews looking for relations with the literature (Creswell, 2014). In the coding phase, we deeply analysed the interviews, selected parts of the text, and assigned them to nodes. The selected nodes have been split into sub-nodes based on the contents. 10 variables were identified following the organizational literature and coded into nodes using NVivo software. We based our methodological approach following (Gioia et al., 2013). This methodology implies a qualitative interpretation of data able to meet the high standard of rigor in research.

Results. We developed a model that demonstrates the pivotal role of organizational activities and the use of communication tools in facilitating learning. This process contributes significantly to the sharing and acquisition of knowledge by individuals. Our results highlight how the learning process unfolds through diverse activities and communication tools, ultimately how forms of learning play a crucial role in shaping in types of knowledge by the end of the process. To achieve this result, we unpacked the learning processes by observing them from different perspectives. In order to ensure a comprehensive perspective on the learning processes, we conducted interviews with both who were acting as mentors, such as the more experienced members, and the learners, including newcomers and apprentices. First of all, we highlighted how learning takes place through the use communication tools. We demonstrate that contextual and vicarious learning mostly occurs with face-to-face interactions. We argued the importance of face-to-face interactions as a learning driver within organizations.

ITC also proven to be a valuable tool for supporting learning, especially reflexive learning. Not surprisingly, reflexive learning is the form of learning through which individuals analyse their owned information, processes, or output. We underlined the importance of learning through the discussion of what they know or do, in order to continuously refine or improve their internal processes. Indeed, the discussion and analysis of their processes or knowledge enabled them to uncover new insights into wildlife behaviours. Perfectly consistent with our obtained results, while face-to-face interactions proved to be relevant for reflexive learning, ICTs also support the process by improving the capacity of communication means and information sharing, especially when group members are working over great distances. Conversely, as we found that reflexive learning occurs in a more balanced manner between face-to-face interaction and ICT-based interaction, the result is not surprising because this type of learning happens more during office activities.

We further demonstrated that various activities have distinct impacts on the learning process. Particularly, our results show how fieldwork-based activities, office activities, and formal education and training activities influence the types of learning differently. Our model demonstrates the fundamental role played by fieldwork-based activities in contextual and vicarious learning. We found that, with minor impact than practice, also office and formal education activities may support learning processes in dynamic contexts.

Finally, we demonstrated how the four typologies of learning impact on explicit and tacit knowledge. Accordingly, experimental and reflexive learning are mostly effective in facilitating the sharing of explicit knowledge as is contextual learning as well. All the newcomers learned to recognize species, acquired knowledge about their behaviours and habits, mastered the use of technologies, and developed skills in surveillance and data collection. This clearly falls into the

category of explicit knowledge. Moreover, contextual learning effectively shapes explicit knowledge while concurrently facilitating the sharing of tacit knowledge occupying an intermediary position. Furthermore, the most significant findings reveal crucial insights in the relationship between vicarious learning and knowledge. We provide evidence that vicarious learning is an effective process that mostly give shape to tacit knowledge.

Research limitations. Even though we provided new insights in learning processes within groups, our study has certain limitations. As it is based on a single case study, it may limit the boundary of findings generalizations. We suggest future studies to replicate this research in other contexts or develop a multiple case study. It guarantees to improve the results by multiplying the patterns found, ensuring the enhancement of robustness of the findings (Yin, 2003)

Since we focused mostly on fieldwork-based and office activities, our findings could be compared by exploring further types of activities. For example, future studies could compare how learning occurs in workplace and during formal education or training programs. We also recommend further research to study more in depth the single typology of learning since more insights could be found at lower levels of analysis.

Managerial implications. Understanding how individuals learn over time while engaged in various organisational activities, may lead to both theoretical and practical insights. This study offers a comprehensive analysis of the occurrence of learning processes in work contexts. Organizations could benefit from our findings since they may improve knowledge sharing and learning processes by actively managing interactions and activities of members.

We highlighted how specific activities and communication tools facilitate learning processes. More specifically, this is achievable by setting specific interactions and indicating the right communication tools for the activities. Indeed, we demonstrated that face-to-face and digitally mediated interactions have different impact on knowledge sharing. For example, organizations can foster face-to-face interactions to improve vicarious learning. Conversely, they can exploit digital communication tools for improving contextual learning. The same applies to the activities: individuals can perform different activities and learn differently. Organizations can recognize the strategic importance of selecting employees for specific activities based on their experience and their level of expertise. By making strategic use of activities to learn, it could help organizations fill in specific weaknesses.

Finally, by linking learning to the type of knowledge, various opportunities emerge. Organizations could indirectly foster the sharing of tacit and explicit knowledge by selectively enhancing specific types of learning.

Originality of the paper. Our model underscores that the presence of the four diverse forms of learning guarantee organizations a seamless knowledge-sharing process, thereby preventing the occurrence of knowledge losses or gaps. Likewise, our model emphasizes the importance of vicarious learning as a facilitator of tacit knowledge; the form of knowledge that, by definition, is the most difficult to transfer and easy to lose (Nonaka & Takeuchi, 1995).

Our results agree the fact that the typologies of activities, associated with different communication tools, facilitates learning processes. For its part, learning shapes knowledge depending on how the entire process is structured, according to the nature of the activities and the interactions.

How do stakeholders perceive the impacts of Nature-based solutions? An Italian case study for coastal restoration and climate change adaptation

GIORGIA CONDOMITTI¹ MARIA ROSA DE GIACOMO² SARA TESSITORE³ MARCO FREY⁴

Abstract

The escalation of natural disasters linked to climate change has underlined the urgent need for effective risk management strategies to mitigate their adverse impacts on communities and economies. To address this, there is a growing emphasis on integrated ecosystem-based approaches, in particular Nature-based Solutions (NBS). NBS offer multiple benefits, including increased resilience and various societal, environmental and economic benefits. However, it is essential to conduct comprehensive evaluations considering both positive (benefits) and negative (costs) impacts across diverse domains. Our study aims to bridge existing gaps in the literature by analyzing potential synergies and trade-offs arising from NBS implementation. Building on previous research, we propose a participatory approach to assess stakeholders' perceptions of the economic, social, and environmental costs and benefits associated with NBS implementation. Through a case study in the Tuscany region as part of the Horizon project Regions4Climate, we seek to categorize stakeholders based on their impact and influence on NBS, providing valuable insights from both theoretical and practical perspectives. The anticipated outcomes include a framework mapping costs and benefits associated with NBS implementation against stakeholder perceptions, highlighting potential trade-offs and synergies, and a novel stakeholder classification based on impact intensity and influence degree.

Key words: *climate change; adaptation to climate change; nature-based Solutions; NBS; coastal flooding; coastal restoration; stakeholder theory; stakeholder engagement; horizon project*

Framing of the research.

Climate Change, coastal flooding and coastal restoration

In recent years, the escalation of disasters stemming from natural hazards, particularly those linked to climate change and variability such as floods, droughts, and heatwaves, has underscored the imperative for effective risk management strategies to mitigate their repercussions on the built environment, communities, and the economy. Over the period from 1980 to 2022, the economic losses inflicted by climate-related events across European member states averaged approximately € 650 billions of which € 59.4 billions in 2021 and € 52.3 billions in 2022 (EEA, 2023).

Erosion and coastal inundation induced by storm surges and waves similarly imperil human infrastructure and ecosystems (Hinkel, et al., 2014). The imperative to reduce risks from coastal storms has catalyzed endeavors to expand the utilization of integrated ecosystem-based methodologies, such as Nature-based Solutions (Van Slobbe, et al., 2013). A growing body of evidence suggests that NBS can effectively mitigate risks (Ferrario et al., 2014; Spalding et al., 2014) by leveraging the inherent capabilities of wetlands, beaches, dunes, reefs, and other natural features to alleviate the impacts of storm surges and waves (Temmerman et al., 2013). Indeed, coastal protection strategies grounded in natural approaches have gained in prominence since they have been incorporated among viable Disaster Risk Reduction (DRR) strategies in several European directives (Council Directive 92/43/EEC, 1992; Directive 2001/42/EC, 2001; Directive 2011/92/EU, 2011; EC, 2009). Natural and nature-based solutions can, thus, fortify the resilience of coastal regions threatened by sea level rise (Borsje, et al., 2011) and coastal storms (e.g., Gedan et al., 2011; Lopez, 2009).

Nature-based Solutions

While the delineation of NBS remains subject to debate (Nesshöver et al., 2017), the prevailing conceptualizations draw upon frameworks articulated by the International Union for Conservation of Nature (IUCN) and the European Commission (EC). IUCN defines NBS as “actions to protect, sustainably manage, and restore natural or modified ecosystems, that address societal challenges effectively and adaptively, simultaneously providing human well-being and biodiversity benefits” (Cohen-Shacham et al, 2016). Conversely, the European Commission characterizes NBS as methodologies to tackle societal challenges with “solutions that are inspired and supported by nature, which are cost-effective, simultaneously provide environmental, social, and economic benefits, and help build resilience” (EC, 2016.)

A common thread among these definitions is their multifunctionality (Kabisch et al., 2016), denoting their capacity to concurrently fulfill multiple functions to deliver a suite of associated ecosystem services that bring benefits to society, the economy, and the environment (Albert et al., 2017). Various additional characteristics proposed in scholarly literature encompass cost-effectiveness (Keesstra et al., 2018; EC, 2016.), adaptability (Cohen-Shacham et al, 2016), a problem-centric approach (Potschin et al, 2016), the utilization of participatory processes for co-design, co-creation, and co-management (Pauleit et al., 2017) and reliance on multidisciplinary, evidence-based strategies (Nature, 2017).

Nevertheless, certain ambiguities persist. A primary challenge involves delineating the boundary between what constitutes ‘nature’ or ‘natural’ and what does not (Nesshöver et al., 2017). Furthermore, the relationship between NBS and established ecosystem-based approaches is contentious (Eggermont et al., 2015; Maes & Jacobs, 2017; Raymond et al., 2017). Another area of contention pertains to the relationship between NBS and innovation, with some asserting the latter as a central tenet of such solutions (Bauduceau et al., 2015; Potschin, 2016), while others omit it entirely (e.g., Cohen-Shacham et al., 2016; Keesstra et al., 2018).

In conclusion, NBS can be conceptualized as an “umbrella term” encompassing a broad spectrum of concepts and practices (Nesshöver et al., 2017; Pauleit et al., 2017). The robustness of NBS lie in its holistic approach to address societal challenges and yield multiple co-benefits (Favre et al., 2017; Nevens et al., 2013). These co-benefits emanate from the multifunctionality of NBS and encompass diverse issues such as augmented landscape values for society, biodiversity conservation, pollution mitigation, enhancement of health and well-being, reduction of GHG emissions, and creation of green jobs (Cohen-Shacham et al., 2016; Raymond et al., 2017). Correspondingly, ecosystem disservices should be construed as co-costs (Calliari et al., 2019). Notably, to comprehensively evaluate the impact of NBS, it is imperative to assess both the positive (benefits) and negative (costs) impacts across various domains, discern their potential synergies and trade-offs, and detect their implications across diverse challenge areas. Moreover, it is essential to account for stakeholder heterogeneity, as it engenders differences in the perception and evaluation of co-benefits.

Stakeholders’ engagement

Numerous stakeholders, defined as “any identifiable group or individual who can affect the achievement of an organization’s objectives, or who is affected by the achievement of an organization’s objectives” (Freeman & Reed, 1983) are involved in concerns regarding the protection of ecosystems (e.g., local authorities, environmental associations, and the local population), whose interests necessitate consideration (Brechin et al., 2002; Kapoor, 2001). Therefore, identifying and addressing stakeholders’ values, interests, and knowledge constitutes a critical step to ensure a well-functioning process and to address potential conflicts, issues, and constraints that may arise.

Previous research has examined the benefits associated with stakeholders’ engagement in environmental management projects. These benefits can be broadly classified under normative and pragmatic arguments for stakeholder engagement in environmental decision-making (Pistorius & Reinecke, 2013; Reed, 2008; Young et al., 2007).

Moreover, the literature on stakeholder participation distinguishes between the degrees of stakeholders’ engagement and establishes a hierarchical nature of engagement ranging from passive dissemination of information to active engagement and transformative participation, implying a preference for higher levels of engagement over lower levels (Arnstein, 1969; Biggs, 1989; Farrington, 2014; Goetz & Gaventa, 2001; Lawrence, 2006; Pretty, 1995). However, recent studies argue that different levels of engagement are likely appropriate in varying contexts, contingent upon the objectives of the work and the stakeholders’ capacity to influence outcomes (Richards et al., 2004; Tippett et al., 2007). Reed (2008) suggests that stakeholder participation may enhance the quality of environmental decisions, with one strong caveat: the quality of a decision heavily relies on the quality of the process leading to it. He advocates for an approach that views participation as a process, emphasizing empowerment, equity, trust, and learning.

Capitalizing on all of this, within the Horizon project “Regions4Climate”, a consortium of experts will implement a Nature-based Solution in Tuscany Region (Italy) aimed at ameliorating the adverse impacts and damages caused by coastal flooding and storms, through a project centered on dune restoration.

Purpose of the paper. Acknowledging the multifunctionality of NBS and their capacity to deliver advantages to numerous stakeholders have become pivotal. Given the involvement of a multitude of stakeholders with distinct interests, and problem understandings in NBS implementation, multiple - sometimes conflicting - values and perceptions coexist.

Many previous studies demonstrate limited capacity to analyze potential synergies and trade-offs arising from the coexistence of different benefits and costs move beyond a compartmentalized assessment, and fail to address how they depend on stakeholder groups considered (Calliari et al., 2019; Narayan et al., 2017; Viti et al., 2022).

Our research seeks to address these gaps providing a more holistic perspective examining the relationships between the various impacts of nature-inspired strategies.

Additionally, we believe that by categorizing different stakeholder on the basis of the level of impact of NBS on them, and the degree of influence exerted by them, we can offer valuable insights from both theoretical and practical

standpoints. Our framework is intended to be a valuable tool for policymakers and decision-makers, enabling a better understanding of local actors' perceptions of NBS and facilitating more effective communication and stakeholder engagement.

Therefore, this paper aims to address the following questions:

1. What are the primary benefits and costs that stakeholders identify within the implementation of NBS for coastal restoration?
2. What synergies and trade-offs can potentially emerge from the aforementioned co-benefits and co-costs according to different stakeholder groups?
3. Based on the analysis of stakeholders' perceptions and interests, how can we classify different categories of stakeholders considering the impacts of NBS and the influence exerted by the stakeholders?

Methodology. To address these questions, we aim to conduct a case study in the Tuscany region of Italy as part of the Horizon project Regions4Climate. The Tuscany project aims to address coastal flooding and consequent adaptation strategies through the implementation of a Nature-based Solution. Specifically, the solution involves the restoration of the dune ecosystem using a nature-based approach, with the project duration spanning from 2023 to 2027.

The case study aims to organize workshops with various categories of local stakeholders during the second year of the project. Hence, this study proposes a participatory approach to assess stakeholders' perceptions of economic, social, and environmental costs and benefits associated with NBS implementation, with a specific emphasis on their capacity to generate co-benefits and co-costs.

Given the objectives of our investigation, we find the case study methodology to be appropriate as it offers flexibility for conducting thorough analyses at localized levels, striking a balance between breadth and depth (Taylor, 2016). Additionally, it ensures a multi-dimensional approach by enabling examination of various facets from diverse perspectives (Eisenhardt, 1989; Yin, 1981).

Stakeholder Selection

The selection of stakeholder groups for analysis was pivotal. The aim was to minimize selection bias and stakeholder marginalization (Ananda & Herath, 2003; Reed et al., 2009). This selection was conducted in a two-stage process. Initially, a panel of experts involved in the project compiled a list of local stakeholders, as summarized in Table 1. Subsequently, this list was validated through data triangulation, drawing from previous academic studies on the subject. The most pertinent categories identified in the literature encompassed public managers and decision-makers (provincial and municipal government), scientific and technical experts, educational institutions, entrepreneurs (directly and indirectly related enterprises), and representatives of social groups and NGOs (Guan et al., 2022; Liquete et al., 2016a)

Table 1. Stakeholders identified by R4C partners (panel of expert discussion).

Identification of Costs and Benefits (in progress)

Similar to previous studies (Calliari et al., 2019; Liquete et al., 2016b; Raymond et al., 2017), we are employing an integrated valuation method that simultaneously considers economic, social, and environmental benefits and costs. Notably, previous works have given limited or no consideration to the conflicts and synergies that may emerge considering the wide range of benefits and costs embedded with NBS (Liquete et al., 2016a; Narayan et al., 2017; Raymond et al., 2017a, b; Reguero et al., 2014). Hence, our framework aims not only to address costs and benefits inherent in NBS but also to highlight potential trade-offs and synergies.

The identification of benefits and costs will be the focus of the workshop that is currently planned for May 2024. The workshop will adopt a participatory approach, fostering interaction among participants. It will comprise two phases.

First, we are planning to divide participants into groups based on their roles: (i) private sector (directly and indirectly related enterprises), (ii) educational and scientific community, (iii) policymakers and political authorities, (iv) representatives of civil society and (v) industry associations. This phase aims to identify specific costs and benefits associated with NBS implementation, considering economic, social, and environmental aspects. Participants will also discuss the significance of these costs and benefits in terms of impacts, their interrelationships, and the likelihood of occurrence.

In the second phase of the workshop, we plan to reorganize the groups into focus groups comprising participants from different roles, who will deliberate on the synergies and trade-offs of costs and benefits previously identified. This phase aims to stimulate discussion and idea exchange among participants and assess the level of consensus reached. It is anticipated that during this stage, the above identified costs and benefits will be further characterized, and the interrelationships between them in terms of synergies and trade-offs will be elucidated.

To prepare participants and facilitate discussion, the focus groups will be preceded by a brief introduction to the project's specific content and objectives, the characteristics of NBS, and a preliminary list of costs and benefits traditionally associated with NBS. This list was compiled through analysis of scientific literature on the topic and encompasses various costs and benefits (see Table 2).

Table 2. Benefits and costs of NBS in the economic, social and environmental domains.

Benefits	Reduce public costs (construction and maintenance costs)	Regulating Ecosystem Services (ESS), Provisioning ESS, Cultural ESS, Supporting ESS, Recreation, Accessibility, Human health and well-being, Green jobs	Habitat quality, Habitat quantity, Habitat creation, Biodiversity, Species abundance, Extent of protected area, Carbon sequestration, Biological control, Pollution reduction	(Liquete et al., 2016a; Cohen-Schacham et al., 2016; Raymond et al., 2017; Ruangpan et al., 2024; Viti et al., 2022)
Costs	Construction costs Maintenance costs	Social cohesion		

Results. Despite their prominence on political and research agendas, the understanding of on-the-ground stakeholders regarding Nature-based Solutions remains limited. Our research aims to enhance understanding of how different stakeholder groups perceive the impact of NBS implementation for coastal restoration across economic, social, and environmental domains. We anticipate uncovering prevailing interests among stakeholder categories and providing insights into the general sentiment regarding NBS application and perceived effectiveness across these domains.

The primary anticipated outcome of the research is a framework capable of mapping the costs and benefits associated with NBS implementation against the perceptions of different stakeholder categories, thereby highlighting potential trade-offs and synergies. This framework aims to transcend the traditional approach that analyzes NBS benefits and costs as isolated entities instead undertaking a comprehensive evaluation of their varied and sometimes conflicting impacts. In doing so, we aim to address the gap identified by (Viti et al., 2022), moving from a compartmentalized assessment of costs and benefits to one that optimizes both the recognition and valuation of the multiplicity of impacts arising from nature-inspired strategies.

Another expected outcome is to devise a novel classification of stakeholders based on two criteria: (i) the intensity of NBS impact on them and (ii) the degree of influence they exert. This classification aims to provide a nuanced understanding of stakeholders' roles and perspectives in the context of NBS implementation.

By identifying the costs and benefits of NBS and the perceptions of key stakeholders, the study aims to support policymakers and public managers with insights on what aspects may spur or prevent the social acceptability of specific NBS.

Research Limitations. The primary limitation of this study pertains to its methodology. While adopting a qualitative approach via a single case study is appropriate for delving deeply into the analysis and offering specific insights, this methodology restricts the generalizability of our findings. To enhance generalizability, replication of our study in diverse contexts for comparative analysis would be necessary.

Another limitation lies in the sampling of stakeholders. Despite efforts to ensure representation across various stakeholder categories through triangulation with categories identified in the literature, bias in the identification of costs and benefits may have originated from the selection of participants.

Additionally, this research solely offers a qualitative assessment of benefits and costs. Extending the study to incorporate quantitative measurements of these costs and benefits, while also evaluating the intensity of synergies and trade-offs identified, would be beneficial.

Managerial Implications. The practical implications of this study primarily target public managers and decision-makers. Our framework concerning benefits, costs, synergies, and trade-offs aids in identifying critical areas and potential conflicting objectives for management, as well as opportunities for strengthening synergies. Thus, the study aims to furnish best practices and solutions for minimizing conflicts and maximizing benefits. Moreover, stakeholder analysis can furnish valuable insights for local authorities to: (i) raise awareness and foster a comprehensive

understanding of NBS among diverse local stakeholders, (ii) structure and tailor communication more effectively based on different stakeholder groups, and (iii) pinpoint additional opportunities for stakeholder engagement.

Originality of the Paper. This research makes original contributions to both theoretical and practical domains. Theoretically, it enriches the literature on stakeholder perception analysis related to NBS implementation by exploring the interrelationships between costs and benefits. While previous literature has focused on identifying diverse costs and benefits from stakeholders, limited efforts have been made to capture potential synergies and trade-offs among them. Furthermore, prior studies often categorized stakeholders solely based on their social group affiliations. However, our study advances this by offering holistic insights into stakeholder views, perceptions, awareness, and expectations of NBS in terms of economic, social, and environmental dimensions. We, also, introduce a novel classification of stakeholders considering (i) the intensity of NBS impact on them and (ii) their degree of influence.

Una ipotesi di formalizzazione markoviana della dinamica delle unità operative nei cambiamenti organizzativi di ENEL S.p.A.

MARIO BRUNETTI¹ GIANLUCA VAGNANI²

Abstract

Il presente studio sviluppa una metodologia attraverso la quale valutare la dinamica delle strutture organizzative delle imprese, in particolare se questa dinamica si basa su un processo di Markov. La proposta metodologia è stata applicata al caso ENEL S.p.A. I risultati segnalano che rispetto a due dimensioni di merito, (dimensione e efficienza), solo la prima presenta un carattere sostanzialmente Markoviano. I risultati suggeriscono che l'efficienza delle unità organizzative è fortemente dipendente dal passato e quindi anche più difficilmente modificabile, anche in contesti strategici di rapido cambiamento.

Parole chiave: struttura organizzativa, dinamica evolutiva, processi di Markov, ENEL S.p.A.

Inquadramento della ricerca. Nel campo degli studi sull'economia e gestione delle imprese, gli studiosi hanno cercato di comprendere e prevedere le dinamiche delle strutture organizzative, qualificata dalle sue unità organizzative e relazioni tra le stesse, su cui si fonda l'impresa e il suo processo di produzione di beni e servizi (Baum and Singh, 1994; Golinelli et al., 2002; Komander and König, 2024). In questa prospettiva, alcune indagini sulla dinamica delle organizzazioni hanno enfatizzato l'idea di raccontare una storia, una cronologia di fatti accaduti, e attraverso questi accadimenti cogliere quanto singolarmente le trasformazioni si siano adattate o siano state influenzate dal contesto di riferimento, oppure quale può essere stato il contributo sul livello di efficienza di questa o quella struttura organizzativa, e così via (Hunziker and Blankenagel, 2024). A volte i periodi di vita delle singole fasi organizzative sono troppo brevi per un esame complessivo; in tal caso potrebbe essere più utile considerare una intera sequenza di trasformazioni organizzative abbracciando un arco temporale ampio e descrivere alcune caratteristiche salienti della traiettoria del sistema. Probabilmente è questa anche una condizione per comprendere logiche di fondo e "memoria passata" manifestata nel passaggio da una configurazione organizzativa alla successiva o alle successive. Qui per memoria passata dell'organizzazione è intesa, l'insieme di quei fattori che condizionano, limitano o più in generale ancora guidano il comportamento di una riorganizzazione e cosa trasporta con sé un cambiamento organizzativo (Walsh and Ungson, 2009; Sen et al., 2023). Nel contesto delineato, l'impiego dell'analisi markoviana presenta un approccio nuovo, offrendo un'interessante intersezione tra i processi markoviani e la teoria organizzativa. Fondamentalmente, un processo di Markov è un modello stocastico che prevede la probabilità di transizione da uno stato a un altro basandosi esclusivamente sullo stato attuale, ignorando il percorso che ha portato ad esso. Questo attributo, noto come proprietà di Markov, fornisce un quadro per la modellazione di sistemi dinamici che si evolvono nel tempo. Sebbene i processi di Markov abbiano tradizionalmente trovato applicazioni in campi che vanno dalla fisica all'economia, la loro incursione negli studi organizzativi è relativamente nascente. Il fascino principale dell'analisi markoviana in questo contesto risiede nella sua capacità di modellare l'evoluzione delle strutture organizzative, cogliendo i cambiamenti nei ruoli, nelle responsabilità e nelle interazioni (Castillo et al., 2021). L'importanza della struttura organizzativa non può essere sopravvalutata, poiché essa modella la distribuzione di ruoli, responsabilità e autorità all'interno di un'organizzazione (Caselli, 1966; Costa and Nacamulli, 1998). Vari modelli di strutture organizzative, come gerarchico, piatto o a matrice, influenzano in modo significativo l'efficacia e l'efficienza dell'impresa e quindi i suoi risultati correnti e prospettici. Pertanto, comprendere e prevedere i cambiamenti all'interno di queste strutture è fondamentale per la pianificazione strategica e l'efficienza operativa (Cafferata and Cibir, 2000). Tuttavia, l'applicazione dei processi markoviani alle strutture organizzative non è priva di difficoltà. La raccolta dei dati rappresenta un ostacolo significativo, poiché sono necessarie informazioni dettagliate sulle transizioni interne e sui cambiamenti organizzativi.

Obiettivo del paper. Il presente lavoro intende definire una metodologia atta a verificare se i cambiamenti della struttura organizzativa delle imprese segue o meno una dinamica Markoviana. L'obiettivo è stato calato nel quadro di una primaria impresa industriale, ENEL S.p.A., in un suo momento strategico particolarmente turbolento (fase di

e-mail: gianluca.vagnani@uniroma1.it

liberalizzazione del mercato dell'energia e internazionalizzazione del gruppo) che ha richiesto intensi e radicali interventi, anche di diversificazione (Picone and Dagnino, 2016), a più riprese sia a livello di macro-scala del sistema organizzativo nel suo complesso sia incidendo sulle strutture operative territoriali. L'insieme di queste trasformazioni, operate con opportuna sinergia tra strutture centrali e territorio, che hanno riguardato a più riprese l'intera azienda, hanno generato impatti su strutture e persone, generando così un ricco insieme di dati e di informazioni sul quale costruire l'analisi qui proposta.

Metodologia. Un primo approccio per analizzare il processo di evoluzione è stato quello di analizzare, in un'ottica di caso di studio (Yin, 2009), le principali trasformazioni organizzative (geometrie delle strutture, livelli di responsabilità, politiche industriali, dati ecc.) che si sono susseguite con continuità nel periodo di maggiore turbolenza strategica determinando pesanti impatti su strutture e persone coinvolte. L'intero sistema ENEL era sottoposto in quegli anni ad una complessa dinamica sia a livello di macro-scala organizzativa relative agli anni 2003-2005, anche connesse all'acquisizione di società nei primi anni della fase di espansione internazionale di ENEL con ri-allocazione di società o aree di business. Contestualmente anche importanti strutture territoriali erano pienamente interessate. Per maggiore chiarezza espositiva di queste fasi sono stati ricostruiti e qui riportati i seguenti cicli corrispondenti agli anni 1999-2002 e dal 2002 al 2007 caratterizzati da forte turbolenza interna del sistema. La Figura 1 mette in evidenza il complesso intreccio organizzativo delle strutture territoriali di ENEL: le frecce indicano i flussi di comunicazione, le linee continue (verticali e orizzontali) rappresentano i legami gerarchici (linee verticali) o le "parentele" funzionali (orizzontali) tra le strutture. Infine i box corrispondono alle unità organizzative (funzioni, uffici, unità, ecc.).

Fig. 1. Un esempio di dinamica organizzativa che hanno fortemente interessato le strutture territoriali dell'area della distribuzione dell'energia elettrica

Nella rappresentazione Markoviana della dinamica organizzativa del caso considerato si è proceduto a individuare le unità organizzative comuni a tutti i periodi. Questa scelta è legata alla necessità di garantire che gli stati caratterizzanti l'organizzazione dell'impresa mantenessero una propria consistenza nel tempo. Ciascuna unità organizzativa è a sua volta rappresentabile da una n-upla di variabili strategiche di risultato, quali, per esempio, il numero di addetti, le quantità prodotte, numerosità dei clienti interni ed esterni serviti (Mocciaro Li Destri et al., 2012). La nostra serie è quindi rappresentata da una matrice multivariata che, per essere trattabile, richiede un'operazione di sintesi. Quest'ultima è stata svolta mediante l'analisi in componenti principali (Principal component analysis o PCA). L'idea di fondo è che le singole variabili non sono altro che viste differenti dello stesso sistema, ci si attende, quindi, che i loro valori si muovano in sincronia nel periodo analizzato. In termini statistici, nell'ambito di questo comportamento corrisponde all'emergere di poche componenti principali in cui si raccoglie gran parte dell'informazione presente nel campo di dati. La mutua correlazione tra le variabili fa sì che l'informazione inizialmente dispersa nella n-upla delle variabili iniziali possa essere condensata in poche componenti che spiegano una parte rilevante dell'informazione globale del sistema, cioè una "maggior proporzione di varianza spiegata". Per questa loro caratteristica di massimizzazione della struttura di correlazione, le componenti ortogonali tra loro per costruzione, non sono altro che gli assi di un nuovo riferimento cartesiano (factor plane) e indicano le direzioni dello spazio delle fasi dove il sistema multidimensionale si correla maggiormente. La PCA è intesa pertanto come una rappresentazione relativistica, dove i posizionamenti nello spazio delle componenti dipendono dalla storia e dalle caratteristiche degli stessi dati esaminati. L'analisi fornisce semplicemente una "rilettura" statistica dei dati per una loro migliore comprensione, senza imporre scelte a priori, lasciando che ogni cosa emergesse dai dati in modo naturale. È in sintesi un cambio di prospettiva è quindi un modo per trarre il miglior aiuto nella interpretazione dei dati.

La presenza di aggregazioni notevoli nello spazio delle fasi corrisponde agli stati discreti visitati dal sistema nella sua evoluzione e sono appunto le probabilità (frequenze) di transizioni tra questi stati discreti a generare la matrice di

Markov. Con questo formalismo un sistema dinamico viene descritto attraverso la sua matrice di transizione, che rappresenta le probabilità condizionale del sistema di passare da un certo stato i al tempo t a un altro stato j (essendo ammessa anche l'identità $i=j$) al tempo $t+1$. Pertanto un prerequisito per l'applicazione di questa analisi è la possibilità di descrivere la dinamica mediante stati discreti nonché di suddividere il tempo in passaggi ugualmente discreti. Nell'impostazione qui adottata, gli stati discreti sono rappresentati dai valori (positivi o negativi) dei punteggi assegnati alle diverse unità organizzative considerate nel corso del tempo. A tal fine, i punteggi delle componenti sono espressi da variabili standardizzate a media zero e deviazione standard unitaria. Conseguentemente, la serie storica è stata analizzata in termini di probabilità di transizione a due stati (positivo/negativo) dei valori della serie. Le matrici corrispondono ad un diagramma dello spazio delle fasi avente come righe i valori X_t e come colonne i valori X_{t+1} , mentre i suoi elementi corrispondono a quanto osservato come probabilità condizionate $P(X_{t+1}=j | X_t=j, X_{t-1}=j_{t-1}, \dots, X_0=j_0)$ a passi temporali successivi. Il formalismo della matrice di transizione (o TM) è semplice, perché permette uno sguardo immediato alle caratteristiche fondamentali della dinamica studiata: se la storia precedente del fenomeno studiato non ha alcun effetto sul comportamento reale, allora le colonne della TM corrispondono a una probabilità generale dello stato corrispondente e le righe della TM riproducono semplicemente la distribuzione di probabilità tra gli stati. Questo tipo di comportamento viene definito una passeggiata casuale. Al contrario, se c'è una marcata deviazione da questo comportamento puramente casuale, può essere ipotizzato che esista una qualche forma di memoria del sistema e quindi di una misura di trascinamento di logiche organizzative e gestionali/operative nelle varie fasi analizzate. In altre parole, se le matrici di transizione a uno stadio e a due stadi tendono a produrre processi sostanzialmente equivalenti, allora è possibile concludere che il sistema considerato dipende soltanto dallo stato passato e non dalla storia complessiva considerata. Viceversa, differenze significative tra le due matrici di transizione a uno e a due stadi suggeriscono l'importanza della storia passata.

Risultati. Come osservato nella metodologia, il primo passo dell'analisi è l'applicazione della Principal Component analysis sulla n -upla di dati caratteristici delle singole unità organizzative considerate. Preliminarmente, occorre osservare che un punto importante è quello della differenziazione degli autovalori tra le diverse serie di dati: singoli numeri casuali e struttura organizzativa ENEL (vista al livello operativo). Qui per l'analisi delle due serie di dati è stata semplicemente presa a base la loro singola storia, ed appare subito evidente il diverso comportamento dei due sistemi osservando l'andamento delle curve riportate nel grafico (scree plot).

Fig. 2. Scree plot degli autovalori della serie di numeri casuali (linea nera solida) e di ENEL (linea tratteggiata grigia)

La Figura 2 mette a confronto gli autovalori (eigenvalues) della matrice di correlazione – proporzione di varianza spiegata da ciascuna componente – relativa a due diversi sistemi molto differenti: un sistema completamente stocastico (sequenza dei numeri estratti da una lotteria- punteggiata in triangoli), e il set dati relativi al sistema organizzativo (ENEL)-strutture operative. Assistiamo in questo caso ad una distribuzione degli autovalori (eigenvalues) della matrice di correlazione (proporzione di varianza spiegata) del tutto diversa, tanto da poter individuare nel caso ENEL una serie di fattori da “trattenere” per l'analisi, cercando i valori più grandi fino al punto in cui sono ben distinti e separati dagli autovalori più piccoli, che è possibile trascurare. I dati in Tabella 1 mostrano tra l'altro i valori della varianza spiegata cumulativa (cumulative explained variance) al crescere del numero delle componenti estratte. In particolare le prime tre componenti principali spiegano da sole già il 90% della variabilità totale del sistema organizzativo in studio.

Tab. 1. Autovalori (Eigenvalues) della matrice di correlazione e relativa proporzione di varianza spiegata

Component	Eigenvalue	Proportion	Cumulative
1	5,015	0,557	0,557
2	2,383	0,265	0,822
3	1,243	0,138	0,901
4	0,143	0,0159	0,976
5	0,090	0,0103	0,986
6	0,067	0,0074	0,993
7	0,052	0,00575	0,999
8	0,007	0,00078	1

Come era da attendersi per un sistema complesso organizzato come quello in esame l'analisi può essere focalizzata sulle prime tre componenti principali accettando una piccola dispersione dell'informazione contenuta nel sistema (10% circa) distribuita nelle altre componenti minori, tutte con valori singolarmente trascurabili e tali da poter essere considerate un rumore di fondo della serie dati. Decisa questa fase di analisi è necessario entrare ora in merito alle correlazioni tra le componenti (factor) e le variabili originali riportate nella matrice dei factor loadings (cfr. Tabella 2). Le variabili maggiormente correlate con le componenti forniranno gli elementi necessari per assegnare un significato alle componenti estratte. Questo è un passaggio fondamentale dell'analisi in componenti principali, quello di attribuire un significato (dei concreti legami relazionali) alle componenti estratte, sulla base sul "profilo dei loading", cioè sulle correlazioni tra le variabili originali e le componenti.

Tab. 2. Matrice dei factor loadings: coefficienti di correlazione fra variabili originali e componenti (Factor)

variabili	Factor1	Factor2	Factor3
Clienti	0,882	0,412	0,128
Rete	0,744	0,382	-0,490
Densità (Clienti/Rete)	0,153	0,003	0,976
Addetti totali_unità	0,874	-0,476	0,035
Impiegati	0,801	-0,551	0,066
Operai	0,913	-0,354	-0,006
Clienti /Addetti totali	0,067	0,945	0,158
Clienti /addetti area distribuzione	0,665	0,721	0,046
Addetti unità/Addetti area distribuzione	0,987	-0,010	-0,017

Esaminando meglio i singoli valori della matrice dei factor loadings si nota come la prima componente mostra valori tutti positivi e questo conferma che il sistema presenta un fattore di scala in cui una grandezza influenza tutti gli altri indici. La prima componente (Factor 1) ha un coefficiente di correlazione vicino all'unità (massimo teorico) con le variabili Operai, Impiegati e Addetti totali, correlazioni molto elevate si osservano anche con le variabili Clienti e Rete. L'analisi si riferisce alle unità territoriali ENEL (Zone) ed è facile associare alla prima componente una misura di "Dimensione" delle unità. Il fatto poi che questo fattore sia registrato sia in termini di clienti sia in termini di numero di addetti, ci conforta su una sostanziale "coerenza media" fra dimensione organizzativa ed esigenze del territorio. Questa prima componente esprime quindi una sostanziale "variazione coerente" tra abitanti, clienti e impianti. Coerenza che è più evidente nel profilo dei loading di Factor 1, dove il numero di addetti delle unità è in linea con il numero dei clienti (0,874 vs. 0,882). La seconda componente (Factor 2) invece è molto correlata con due "variabili rapporto": clienti/addetti e clienti/addetti area distribuzione; essa è quindi direttamente rappresentativa dell'efficienza operativa differenziale tra le diverse unità poiché scala con la quantità di 'operazioni' per addetto. In termini fisici chiameremo la prima componente, l'intensità e la seconda la derivata di un campo. La terza componente (Factor 3), infine, è rappresentata dalla "pura" densità della copertura della rete elettrica sul territorio (massima correlazione con la variabile clienti/rete). Questa componente riflette le caratteristiche fisiche del territorio e conseguenti specificità legate alla tipologia di popolamento (aree più o meno rurali, presenza di aree industriali). Dipende insomma dalla morfologia fisica (e quindi dalla densità abitativa) del territorio ed è riconducibile a quello che possiamo chiamare "effetto territorio". Quest'ultima dimensione, data la sua natura esogena, non è stata ulteriormente considerata nell'analisi della dinamica Markoviana della struttura organizzativa di ENEL. Queste nuove dimensioni del sistema, indipendenti l'una dall'altra (per costruzione), forniscono una sorta di "regolarità dal basso". In altre parole, ogni componente equivale ad una struttura di relazione che il sottoinsieme di dati fa emergere come "regolarità", ed in sostanza riassume un concetto autonomo che raccoglie al suo interno uno schema di relazioni particolari (profilo di loading) tra le variabili originali. Il passaggio dalla serie dati alle componenti ha permesso in fondo di confrontarci con un segnale più chiaro rispetto alla serie dati originaria e comunque mantenere collegate le informazioni alla dimensionalità del sistema. Abbiamo pertanto a questo punto la possibilità di caratterizzare la dinamica lungo i factor score delle componenti trattate in termini di un processo markoviano al fine di verificare la possibilità di una caratterizzazione probabilistica della dinamica del sistema. In particolare, rispetto ai due fattori considerati, "Dimensione" e "Efficienza", si è proceduto alla costruzione delle matrici di transizione a 1-passo e a 2-passi. Le matrici sono riportate di seguito nelle Tabelle 3 e 4.

Tab. 3. Matrice di transizione calcolate sull'intero periodo 1997-2007 per il fattore "Dimensione"

1-passo			2-passi			
	>0	<0			>0	<0
>0	0,180	0,819	>0	>0	0,583	0,417
<0	0,388	0,611	>0	<0	0,581	0,419
			<0	>0	0,311	0,689
			<0	<0	0,038	0,962

Tab. 4. Matrice di transizione calcolate sull'intero periodo 1997-2007 per il fattore "Efficienza"

1-passo			2-passi			
	>0	<0			>0	<0
>0	0,944	0,055	>0	>0	1	0
<0	0,427	0,572	>0	<0	1	0
			<0	>0	1	0
			<0	<0	0,723	0,277

Sulle matrici di transizioni a 1 e 2-passi è stata poi simulata, in 1000 prove indipendenti, l'evoluzione dei due fattori. Le serie simulate originanti dalle matrici a 1 e 2-passi sono state comparate attraverso il test non parametrico di Kolmogorov-Smirnov (K-S). Da questo test si osserva che rispetto al fattore "Dimensione" le due serie simulate generate dalle matrici di transizione a 1 e 2-passi sono differenti, sebbene con un livello di confidenza del 95% (Combined K-S = .461, $p=0.02$). Rispetto al fattore "Efficienza", le differenze sono assai più marcate e significative (Combined K-S = .1671, $p<.0001$). Dunque, rispetto alla "Dimensione" il processo presenta dei tratti tendenzialmente Markoviani, con la storia recente che è sostanzialmente rilevante. Differentemente per il fattore "Efficienza", in cui la sostanziale differenza dei risultati dell'evoluzione del sistema così come ottenuta nelle matrici a 1 e 2 passi, evidenzia che la storia passata è assai rilevante e condizionante la dinamica futura.

Limiti. Il presente lavoro si basa su un caso di studio, sebbene rilevante, in un periodo di intenso cambiamento, che tuttavia fornisce un laboratorio interessante per cogliere le variazioni organizzative e quindi rappresentarle in un'ottica di processo Markoviano. In aggiunta, la dinamica organizzativa di una impresa è influenzata da condizioni specifiche della tecnologia di produzione così come di fattori istituzionali di conteso. In questo senso, la sostanziale dipendenza dal passato dell'efficienza potrebbe essere il portato di inerzie che traggono origine dal contesto istituzionale di riferimento, così come dalla tecnologia di produzione adottata. In questo senso, studi successivi potrebbero adottare la metodologia proposta a casi diversi operanti in settori e contesti diversi, valutando, così, come fattori specifici a livello di impresa, settore e contesto istituzionale sono in grado di spiegare la Markovianità o meno di determinati processi a livello di struttura organizzativa di una impresa.

Implicazioni manageriali. Le organizzazioni sono fatte di persone e dalle persone, e sono proprio loro a mantenere sia la memoria delle trasformazioni che ad attuare il cambiamento stesso una volta che ne abbiano assimilato e fatta propria la necessità. Il lavoro proposto e l'approccio Markoviano delle dinamiche organizzative delle unità territoriali di una importante area di responsabilità di ENEL (area della distribuzione) e che copre un decennio di grandi cambiamenti vuole essere principalmente un tributo alle tante persone (circa 40000 persone coinvolte a più riprese) che con tutte le loro speranze e aspirazioni, ma anche preoccupazioni, ebbero la forza di mettersi in gioco (con cambi di responsabilità, luogo di lavoro). Un elemento iniziale da richiamare riguarda la differenza tra il fattore Dimensione (Factor 1) dove è più "facile" indirizzare strategie e comportamenti con cambiamenti di percorso anche abbastanza repentini, (maggiore possibilità di agire sulla leva dimensionale delle unità organizzative), mentre per quanto riguarda i complessi e "sensibili" meccanismi di gestione legati all'efficienza operativa (Factor 2), strettamente connessa alla risorsa "Personale", il sistema mostra maggiore resilienza e quindi minori "gradi di libertà". Questa minore plasticità della variabile "Personale" crediamo sia da leggere anche nella salutare presenza di garanzie per i lavoratori occupati.

Originalità del paper. Il presente lavoro introduce una metodologia per indagare il carattere Markoviano dei processi di evoluzione della struttura organizzativa di una impresa in presenza di cambiamenti strategici. Questa metodologia non è limitata al caso di studio considerato, bensì può essere estesa ed applicabile a casi diversi. Il nostro contributo offre anche evidenze empiriche sulla dinamica delle organizzazioni, evidenziando come la storia passata influenza questa dinamica in modo differente in funzione del parametro di misura considerato.

Empowering women workforce in steel production: A case study on implementing Diversity, Equity and Inclusion (DEI) initiatives

LAURA TOLETTINI¹ ELEONORA DI MARIA² EMILIA FILIPPI³ LETIZIA LO PREIATO⁴
MARIAASOLE BANNÒ⁵

Abstract

The steel industry is facing numerous challenges. The most well-known are related to environmental sustainability, but fewer know how social challenges are growing in importance, especially those related to Diversity, Equity and Inclusion (DEI). The pursuit of new skills and competencies, along with the establishment of a more equitable environment, even in traditionally male-dominated sectors like the steel industry, aims to foster a more sustainable economic system. A path on DEI can become a strategic business lever, especially if we think about opening new job market opportunities by experimenting with women's empowerment in production. To understand the importance of DEI initiatives, we present and analyze the case study of SpectrumSteel Industries⁶, a leader in the European steel market. The introduction of DEI initiatives in SpectrumSteel Industries is still ongoing. Still, results highlight that women's competencies can bring positive impetus to a historically male-dominated sector, also enhancing the importance of more automated processes and machines, underscoring benefits for the whole population.

Key words: *Steel industry; Diversity, Equity and Inclusion initiatives; Women in production; Case study*

Framing of the research. *The steel industry represents an essential industrial and economic sector, embracing a range of products which are indispensable every day (World Steel Association a 2023). The steel industry is the backbone of the European economy (Eurofer 2022). The European Union (EU) was established as a result of the pivotal role played by steel. In 1951, the founding states of the EU signed the treaty of the European Coal and Steel Community, which aimed to collectively manage the coal and steel industries. The European steel industry is guiding the world through its commitment in technological and digital innovation and environmental sustainability (Eurofer 2023). The EU steel sector employs about 306,000 highly-skilled people and has a turnover of around €130 billion, with an average yearly production of 152 million tons of steel per year and more than 500 steel production sites (Eurofer 2023). Germany and Italy are among the first twenty top world producers (World Steel Association b 2023). Specifically, in 2022 Italy maintained its 11th position among the world top producers, with 21.6 million tons (16% of the world production) (Federacciai 2022).*

The steel industry is recognized to be a male-dominated industry, where the definition of male-dominated refers to the lack of presence of women at all levels of the organization, from managers to employees (Australian Human Rights Commission, 2013; Salminen-Karlsson 2020). Increasing the number of women in the steel industry is not only an issue about the abolition of gender segregations, and reaching the Agenda 2030 goals, but also an opportunity to attract different skills and competencies (Torre 2017; Salminen-Karlsson 2020). Unfortunately, introducing women in a male-dominated industry is not simple as hiring other worker categories. Women often represent the minority and this may have negative consequences such as exclusion dynamics, greater stress, discomfort, and isolation (Salminen-Karlsson 2020; Torre 2017).

⁶ *SpectrumSteel Industries is a fictitious name used to maintain anonymity.*

Group dynamics are primarily influenced by the size and composition of the group. In such dynamics, the minority individuals often find themselves isolated or compelled to conform to the majority's behavior (e.g. Kanter in 1977, Tanford and Penrod 1984; Mathisen et al. 2013). Moreover, people in the minority group are often seen as tokens (Kanter 1977, Torre 2017; Salminen-Karlsson 2020). The concept of token was introduced for the first time by Kanter (1977): when a minority is introduced in a homogeneous group, it is perceived only through the “diverse” character. When diversity is given by gender, women are identified only by their sex, men emphasize this difference, and gender stereotypes are exacerbated (Konrad et al. 2008). All these mechanisms enhance women's pressure and their perception of being “controlled” (Kanter, 1977; Torchia et al., 2011; Holgersson and Romani 2020). In addition to the underrepresentation of women, the presence of masculine norms in an organization is another important mechanism that exacerbates the tokenism faced by women (Holgersson and Romani 2020; Salminen-Karlsson 2020). Masculine norms are the processes by which men's experiences, point of view and subjectivity become universalized and accepted as a common way of life (Lewis and Simpson 2012). Moreover, masculine norms contribute to maintaining hidden male-privilege and identifying the minority group as a threat that can challenge this situation of privilege (Lewis and Simpson 2012). This leads to the possibility that the majority group (i.e., men) do not accept the minority group (i.e., women) and obstacles it, making it invisible (Salminen-Karlsson 2020).

In this unbalanced situation, organizations have a decisive role. The cultural orientation of organizations can greatly influence women's work experience and encourage them to enter and remain in male-dominated industries (Harman and Sealy 2017). This cultural orientation encompasses various factors that can enhance the inclusion of women such as management style (e.g., equity, informality, flexibility), language and communication, and gender awareness (e.g., recruitment, ambassadors), background attributes (e.g. location, ownership and workplace organization) (Rutherford 2001; Holgersson and Romani 2020). Implementing these types of measures can interrupt the perpetuation of masculine norms, expose these norms, and openly challenge them, suggesting that the organization perpetuates a gender equity narrative (Holgersson and Romani 2020). Although at the beginning the majority group (i.e., men) may not agree with these actions, this orientation perpetuated from the management team (reflected also in operational actions) becomes a reference point for employees' behaviors (Holgersson and Romani 2020). This sort of normative control forces employees to internalize gender equality culture, promoting a comfortable environment for both men and women (Holgersson and Romani 2020).

To effectively promote Diversity, Equity, and Inclusion (DEI) within the organization, it is crucial to develop a comprehensive strategy that focuses on increasing the representation of women in the workforce. Several workplace initiatives and mechanisms can be introduced in particular in four areas: attraction, recruitment, retention, and development (Australian Human Rights Commission 2013). Specifically :

- Attraction strategies aim to remove the negative perception that women may have about male-dominated industries and, more generally, men and society have about women's presence in these industries. Their purpose is also to promote the benefits of working in these industries and the existing career prospects;
- Recruitment strategies are designed to verify if the existing interview and selection process is already inclusive or if it needs to be changed in this direction. Another objective is to expand the range of skills that potential candidates, especially women, are expected to possess;
- Retention strategies aim to change firm's culture towards DEI and to maintain it during the employment and career development;
- Finally, development strategies are put into action to establish a promotion system that is both transparent and inclusive. This system aims to provide women with the opportunity to participate in the necessary training and development programs in order to progress in their careers within the company.

Within these four areas, several initiatives can be designed and implemented. Their identification and success strongly depends on the objectives and characteristics of the steel mill.

Purpose of the paper. This paper aims to describe and analyze how SpectrumSteel Industries⁷, a steel mill operating in Northern Italy, has introduced DEI initiatives and what are the initial results obtained.

The origins of SpectrumSteel Industries can be traced back to a long-standing steel tradition, spearheaded by a woman who was the mother of the company's founder. She played a significant role in managing the family forge during the 1940s. In the Fifties, the founder took over the family forge. Later, SpectrumSteel Industries expanded until the first new steel complex was created, comprising two steel plants and two rolling-mills running in two different sites not far away from each other. From the Eighties, SpectrumSteel Industries focused its development into four streams: internationalization with the acquisition of production sites in Europe, verticalization to integrate the entire production cycle, and diversification by enlarging the core business of standard construction steel into special steel, and sustainability with a particular attention to environmental protection and work quality improvement. Today, SpectrumSteel Industries has a production capacity of more than 2 million tons of steel per year, by employing more than 1,500 employees in Europe and registering more than 2 billion euro of turnover (SpectrumSteel Industries 2023).

SpectrumSteel Industries operates in Northern Italy, which has a long tradition in steel production (Fondazione Biblioteca Archivio Luigi Micheletti n.d.). SpectrumSteel Industries is based in a province with a long tradition in steelmaking. This province is currently leading the steel industry in Italy (Fondazione Biblioteca Archivio Luigi Micheletti n.d.). In 2011, the women employment rate in this province was 40.1% compared to 56.9% of the men workforce (Istat

⁷ SpectrumSteel Industries is a fictitious name used to maintain anonymity.

2011). In Italy, the employment rate of women aged 20-64 years old was 55% at the end of 2022, under the EU average of 69.3% (Eurostat). The Italian average of women employment is one of the lowest among EU states (Eurostat 2022).

The Italian steel industry employed 30.4 thousand employees in 2020 and was the second largest steel market in the European Union (Federacciai 2021). This sector has a great potential of opening its labor market to women workforce: 92% of the workforce consists of men, while women account for only 8% (Federacciai 2021). This gender composition is a result of the cultural heritage of the sector, well-known as a male dominated sector, despite its technological development in the field of a more automated and safer workplace (Federacciai 2021). Nevertheless, during the 2018-2020 period, women employment increased by 1.9%, while men employment decreased by 1.8% (Federacciai 2021), revealing how the engagement in such a diversity topic could have great economic potential for such a sector. Recent research discussions are focused on how Industry 4.0, in particular automation, can be potential enablers of equal work in terms of gender (Metha et al. 2021).

The description of the context in which SpectrumSteel Industries is active underscores how the introduction of DEI initiatives has taken place within an industry of significant employment importance. However, SpectrumSteel Industries operates in an industry where the women workforce comprises less than 10%, and even less if we consider data on primary steel route (i.e. core production, such as still mill and rolling mill) (Istat 2021). The context in which SpectrumSteel Industries operates makes this case study particularly intriguing, as the firm has had to confront two types of resistance in promoting women's employment in production: one stemming from the industry itself and the other from the broader operating context.

Based on this premise, this case study aims to answer this research question: How can a DEI policy be effectively implemented within a firm operating in a male-dominated industry, starting from management awareness (on topics like attraction, recruitment, retention and development) and extending to the implementation of DEI initiatives?

Methodology. The methodology adopted for this case study is described with regard to data collection and data analysis.

Data collection. Three data sources were used to gather relevant information. Data collection began with archival data such as non-financial disclosure, website, and generalist and specialized press (Vaara and Lamberg 2016). These sources were extremely useful to familiarize with the setting as they describe SpectrumSteel Industries, its production activities, and its DEI initiatives.

We also conducted 11 semi-structured interviews with firm owners, top managers, and middle managers. We selected this interview format because it allows for an unrestricted and thorough expression of viewpoints, facilitating the gathering of diverse insights regarding the decision-making process that prompted SpectrumSteel Industries to embark on DEI initiatives (Rowley 2012). We interviewed people in different hierarchical positions and with different functional roles to explore their different points of views and to collect insights about the strategic, managerial, and operating issues (i.e. attraction, recruitment, retention, development) regarding the introduction of DEI initiatives (Bryman and Bell 2015).

Before the interviews, we met the interviewees several times to establish a trusting relationship (Mellon 1990). Relying on previous studies, we developed an interview guideline to cover all pertinent topics, which was shared with the interviewees before conducting the interview.

During the interviews, we implemented a courtroom-style procedure and ensured that at least one of the authors was present with the aim of mitigating subjectivity (Bingham and Eisenhardt 2011). We also tried to collect detailed information by posing additional questions or asking for clarification if necessary.

Particular attention was paid to achieving convergence through data saturation (i.e., to achieve a point where further data collection is unnecessary as no additional information is being found) (Glaser and Strauss 1967; Saunders et al. 2017).

Concurrently with the collection of archival data and the interviews, we visited the plant several times to directly observe the fieldwork (Corbetta 2003). This deepened our understanding of the context as we observed the behavior and reactions of top and middle managers and employees during the process of introducing DEI initiatives.

The integration of several types of data (i.e., archival data, interviews, and direct observation) is considered essential to understand management phenomena (Argyres et al. 2020). Moreover, this integration enabled data triangulation, i.e., comparisons between information obtained from different sources (Lee et al. 1999).

Data collection lasted more than one year. The collection of longitudinal qualitative data enabled us to develop a process model (Glaser and Strauss 1967; Langley et al. 2013) describing the entire process.

Data analysis. To mitigate interpretation biases, only a subset of the authors utilized the transcribed notes to reconstruct the process of introduction of DEI initiatives and the behavior and reactions of firm owners, top managers, and middle managers (Corbin and Strauss 2015).

Results. SpectrumSteel Industries started its DEI path with the Code of Ethics in 2018, establishing that discrimination is not accepted within the firm. In 2020, SpectrumSteel Industries subscribed to the Charta for gender equity and no discrimination in the workplace. This Charta is a declaration of intent, voluntarily signed by firms of all sizes, for the dissemination of a corporate culture and inclusive policies, free of discrimination and prejudice, capable of valuing talent in all its diversity. In 2021, SpectrumSteel Industries created a DEI policy to promote an inclusive leadership, gender equity in the workplace, a global culture in firm plants, and firm's responsibility towards its internal and external community. In 2022, the firm introduced a Sustainability Committee to pursue ESG scorecards supporting

the industrial plan of the Group, with DEI values playing an important role. In 2023, the Diversity, Equity, Inclusion and Welfare division was created with the goal to gradually implement a DEI strategy and collect all current projects under the main categories of the policy.

SpectrumSteel Industries views the enhancement of diversity, equity, and inclusion (DEI) as a crucial component of its ESG (Environmental, Social, and Governance) strategy. This strategic focus aligns with the company's history, purpose, and vision to foster growth and cultivate positive relationships with employees and external stakeholders, such as suppliers, customers, and local communities. By prioritizing DEI, SpectrumSteel Industries aims to create new opportunities for market expansion and the recruitment of talented individuals.

In the following paragraphs, we present the results in the efforts of SpectrumSteel Industries to create an equal working environment, by considering the whole employee lifecycle (attraction recruitment, retention, development), and especially starting by the experience of female workforce in the primary steel route. We also report some extracts of semi-structured interviews, which were processed by integrating archival data and direct observation⁸.

Within the next 4 years, SpectrumSteel Industries aims to register a level of women occupation that is ten times the mean value in the steel industry in the primary route. To reach this goal, SpectrumSteel Industries is implementing several initiatives to orient the organizational culture towards DEI and increase women's presence in the workforce.

“For me, gender equity is breaking down an open door. I believe you can find greater efficiency with people of different genders at the workplace” (Interviewee B - Director - Production)

“Women in production means for the steel sector enhancing its business continuity, to guarantee a future for the next generations of our sector. I have to open my context to other people, not only men... This means a cultural change” (Interviewee E - Director - Sales).

Since the beginning, SpectrumSteel Industries has been aware of the challenges implied in this cultural process, including the long journey required and the eventual difficulties to be faced in order for the change to be accepted.

AN ORGANIZATIONAL CULTURAL PATH TOWARDS DEI THROUGH FEMALE WORKFORCE EMPOWERMENT.

In order to disseminate the DEI values throughout the company, SpectrumSteel Industries established a team of DEI ambassadors who represent all subsidiaries of the Group. Its task is to identify the opportunities and challenges regarding DEI topics. Specifically, this group should recognize the value of diversity and share experience in the organization, actively promoting and upholding DEI principles within the firm and in the future with stakeholders in the value chain (from suppliers to customers), propose shared and constructive solutions to make corporate governance increasingly inclusive, actively contribute to internal communication of DEI issues, and communicate business issues in an inclusive manner.

In addition to the establishment of this group of DEI ambassadors, other initiatives have been undertaken to orient the organizational culture towards DEI. A four-year training program on DEI topics has been introduced for the entire workforce, from firm executives to blue-collars. International experts on DEI issues have been engaged, and an innovative coaching methodology has been employed, starting from individual resources on inclusion already present in everyone (a so-called “inclusion x-factor”⁹). Managers and executives benefited from a supplementary and more specialized training program to ignite the change towards DEI.

Although women were already employed as crane drivers and quality laboratory technicians in some subsidiaries, the parent firm still had a significantly low representation of women. SpectrumSteel Industries therefore decided to design, together with a qualified partner, a program aimed at introducing women in production starting from the parent firm. The big challenge in this program is to specifically introduce women in the primary steel route, completely male-dominated. The program began in 2023 and is still in development. To date, some positive results have already been recorded and some women workers have been employed in production. Consequently, the parent firm decided to make a further implementation in other subsidiaries. Specifically, to increase women's presence in production in the primary steel route, SpectrumSteel Industries designed some initiatives in four areas, accompanied by a consultancy firm specialized on DEI issues: attraction, recruitment, retention, and development. We specify that SpectrumSteel Industries is planning a technological shift to reach decarbonization goals, with a massive investment plan in different strategic sites, thus needing to open to new competences and job market opportunities, like targeting women and people with different ethnicities.

ATTRACTION. Among attraction strategies, SpectrumSteel Industries started with an analysis of jobs in primary steel route from different perspectives. This analysis was performed by an internal task force composed of different functions with the aim of assuring job positions for women also according to normative, security and health conditions.

With the goal to be successful in such a new project of empowerment of female workforce in the heart of steel production, SpectrumSteel Industries collaborated with a reputable partner to showcase employment prospects. It also implemented proactive actions such as a LinkedIn campaign and Open Days to change firm image and appeal to women candidates and in this way, it successfully attracted over hundreds of women candidates.

⁸ Extracts from interviews: A, B, D (Directors of production), C (Energy manager), E (Sales Director), F (General Manager).

⁹ The inclusion x-factor is meant to be the inner and natural resource and attitude of integration possessed by anyone of us.

“Today's steelmaking is different: safer, digital and more inclusive than in the past. And not only to women. Talent and merit know no gender.” (Interviewee F - General Manager)

RECRUITMENT. Recruitment strategies are designed to assure that the selection process is inclusive and to broaden the skills required of women potential candidates. In this regard, the Human resources department of SpectrumSteel Industries is thinking about improving women recruitment not only in primary steel route production, but also through the recruitment of young women as technicians and engineers.

“If we want more women in production, we have to modify our recruitment process and to make some internal organizational changes. We see women are now attracted by jobs once were of men. For example crane drivers, from an operative and mentality point of view, women can be more efficient than men.” (Interviewee D - Director - Production)

Furthermore, a new project together with a network of other partners has been launched to create a model of recruiting and retaining individuals from vulnerable or disadvantaged backgrounds, aiming to provide opportunities for those often overlooked in traditional hiring processes.

RETENTION. Retention strategies aim to change organizational culture towards DEI. The group of ambassadors has the main objective of orienting the organizational culture towards DEI, contributing with initiatives and suggestions to the future design of a more structured firm's DEI strategy. This group has organized sensitization campaigns to raise awareness against gender-based violence and the “Friday of Inclusion”, a monthly newsletter aimed at raising awareness of DEI topics with the help of well-known movies. Moreover, after the periodical internal climate survey, some measures in hourly flexibility (i.e., part-time and home working) were made available by the organization for newly become parents. Lastly, several women-friendly initiatives have been introduced, including the modifications to the toilets and changing rooms to make them more comfortable for women, parking lots near the exits reserved for women, and free medical screenings (e.g., breast cancer control).

Concerning the project of female empowerment in primary steel route jobs, several were the moments of focus groups and coaching sessions both for male and female colleagues, in order to accompany the process of cultural change in a historically dominated male world.

“Women have different perspectives and competences who can enrich the organization. I believe in the future we will see a woman as shift leader “ (Interviewee A - Director - Production).

“As a manager, you need to exploit the differences of competences in your employees, also due to gender differences, to have a successful working environment. For years, I have chosen only women employees because they are more efficient. In our company, there are countless positions that can benefit from women's presence, in processes, for example, quality control.” (Interviewee B - Director - Production).

DEVELOPMENT. Lastly, development strategies aim to design a transparent and inclusive promotion system. At the very beginning of the working experience, a training program on steel production is offered to groups of new workers, to acquire all the relevant information and competences about steel making. In the specific case of female workforce in the primary steel route, an individual coaching was offered periodically to women in order to make them aware of challenges and potentials of the steel environment and obtain more chances of integration within the organization. Moreover, at SpectrumSteel Industries some strategic positions in technical and economic departments are held by women.

“Women do not have first to make limitations on themselves at the workplace, on their career. As a woman, I do not give such a great importance to gender differences.” (Interviewee C - Manager - Energy)

Women candidates were actively involved in succession planning paths.

The efforts of SpectrumSteel Industries in its DEI initiatives, especially looking at the empowerment of women workforce in production, may have a great impact not only on the firm's desire to become a more attractive employer for the province, but also on the possibility to open new opportunities in the recruitment and in the job market.

Research limitations. The introduction of DEI initiatives at SpectrumSteel Industries is still in its early stages. Many phases of the project have yet to be implemented. Therefore, it is not possible to make a final assessment of the results, but rather only an interim assessment focused on the initial stages. SpectrumSteel Industries estimates that the final evaluation can only be made in the medium term, in 3/4 years.

Another limitation of this case study is that interviews were especially conducted with the firm owners, top management, and middle management. For a comprehensive evaluation of the effectiveness of DEI initiatives and any improvements to be made, it is essential to gather the opinions of those directly involved, namely women employees. Additionally, it would be intriguing to assess the reactions of male employees towards these initiatives.

Managerial implications. *The analysis of SpectrumSteel Industries's experience in introducing DEI initiatives has several managerial implications. Primarily, it allows us to discern the most effective endeavors and those that have demonstrated negative outcomes, recognize the potential obstacles that may arise during their implementation and strategies to overcome them, and comprehend the workforce's responses to these endeavors. Second, the achievements of SpectrumSteel Industries can serve as encouragement for other steel mills and firms in other male-dominated sectors (e.g., cement, construction, chemical, oil and gas industries) to introduce DEI initiatives aimed at promoting women's presence within the firm. This successful case could serve as a significant catalyst in institutional settings where additional endeavors are required to attain the inclusion of women in traditionally male-dominated environments and positions. Third, this case study could serve as a model for firms looking to undertake DEI initiatives.*

Originality of the paper. *SpectrumSteel Industries represents a highly valuable case study to be analyzed and evaluated. SpectrumSteel Industries is the pioneering steel mill in Italy to implement DEI initiatives in the steel industry, specifically aimed at promoting women's participation in production. Despite facing resistance from both the male-dominated industry and the broader operating context, SpectrumSteel Industries introduced these initiatives. The industry has a low percentage of women employment, while the overall employment rate for women is significantly lower compared to men. These initiatives were introduced despite SpectrumSteel Industries facing two types of resistance: one stemming from the industry itself, which is a male-dominated industry with a low percentage of women employment; one stemming from the broader operating context, characterized by a substantially lower women employment rate compared to that of men.*

La trasformazione organizzativa di Autostrade per l'Italia: verso la strategic agility nell'era delle policrisi

PAOLO BOCCARDELLI¹ ROBERTO TOMASI² CHIARA BARTOLI³ MARIA LORENZA GERARDI⁴

Abstract

Il caso studia la trasformazione organizzativa di Autostrade per l'Italia (ASPI), azienda leader a livello europeo nella costruzione di autostrade e servizi di mobilità. L'analisi individua i fondamenti del contesto meso, micro e macro che hanno attivato la trasformazione dell'organizzazione in chiave agile. Vengono approfonditi gli aspetti rilevanti della trasformazione, e che hanno permesso al Gruppo di costruire nuovi equilibri per assicurare continuità nella creazione di valore sostenibile condiviso, anche nella discontinuità generata da shock esterni ed interni. Il caso mira a favorire la comprensione dei fattori che presiedono alla creazione della agility e intende fornire ai manager e agli studenti una guida alla comprensione dei processi di cambiamento in contesti dinamici guidati da tensioni paradossali.

Keyword: *agility, paradoxical tensions, strategic change, trasformazione organizzativa*

Tipologia: Caso

Il contesto e gli obiettivi di apprendimento

Le organizzazioni si trovano oggi a rispondere a condizioni di mercato in rapido cambiamento, che sono guidate dai mega-trend del green e del digitale; si tratta di fenomeni in grado di accelerare i processi di trasformazione interna (Uhrenholt et al., 2022) e che agiscono simultaneamente come "transizioni gemelle" (commissione Europea, 2021). Le innovazioni tecnologiche disruptive alterano le strutture di mercato esistenti, influenzano i paradigmi tecnologici e di business e generano cambiamenti profondi nelle strutture organizzative e nelle dinamiche di mercato (Christensen, 1997; Schuelke-Leech, 2018). Si inseriscono in questo contesto anche le sfide legate alle policrisi globali come la pandemia da COVID-19, l'instabilità geopolitica, le dinamiche inflazionistiche, e che sono suscettibili di riconfigurare le catene globali del valore (Marvasi, 2023).

Nel tentativo di innovare e navigare il cambiamento, le organizzazioni affrontano paradossi organizzativi, ovvero tensioni tra forze opposte ma tra loro interdipendenti (Lewis et al., 2014; Dieste et al., 2022). La gestione di queste tensioni richiede una nuova vision, con il superamento degli approcci tradizionali basati sul controllo, per abbracciare modelli più dinamici nei processi decisionali (Smith and Lewis, 2011; Handy, 1994), verso la creazione di strutture flessibili e disegnate secondo logiche agile.

La strategic agility rappresenta la capacità che acquisiscono le organizzazioni di monitorare i cambiamenti e adattarsi dinamicamente ad essi ridefinendo i propri obiettivi in base alle variabili contestuali e ambientali (Morton et al., 2018). L'agilità strategica è diventata sempre più rilevante per le organizzazioni in risposta ai rapidi cambiamenti che si verificano nei mercati e nei business (Girod et al., 2023). Le imprese che riescono ad integrare l'agility nei propri processi decisionali mostrano livelli di operational performance superiori rispetto alle organizzazioni che si muovono secondo i modelli organizzativi tradizionali (McKinsey, 2021). Abbracciare l'agility diviene quindi un elemento chiave per le imprese per accrescere la capacità di mantenere un vantaggio competitivo in contesti dominati della velocità del cambiamento e dall'incertezza.

L'obiettivo del lavoro è quello di presentare il processo di trasformazione di Autostrade per l'Italia verso l'agility in un contesto governato da molteplici tensioni esterne ed interne, al fine di delineare il percorso attraverso il quale le organizzazioni possono raggiungere modelli organizzativi più flessibili e dinamici.

Obiettivi di apprendimento:

- *Comprendere i driver del cambiamento esterni ed interni, a livello micro, meso e macro, che possono condurre le imprese ad attivare percorsi di cambiamento verso l'adozione di modelli organizzativi orientati alla strategic agility;*

³ LUISS

e-mail: cbartoli@luiss.it

⁴ Sapienza Università di Roma

e-mail: marialorenza.gerardi@uniroma1.it

- *Comprendere i building blocks che occorre tenere in considerazione nel processo di trasformazione organizzativa verso la strategic agility;*
- *Riflettere sul valore della crisi come motore di trasformazione delle organizzazioni;*
- *Apprendere i processi attraverso i quali le organizzazioni acquisiscono capacità dinamiche.*

Il caso: Autostrade per l'Italia

1. Autostrade per l'Italia: la storia

La storia aziendale di Autostrade per l'Italia (ASPI) si snoda attraverso quasi sette decenni – dal 1950 a oggi – che ripercorrono anni di cambiamento significativo non solo per il Gruppo, ma anche per l'economia, l'industria e le infrastrutture dell'Italia. Negli ultimi settant'anni, infatti, ASPI ha accompagnato l'Italia nei cambiamenti guidati dalle trasformazioni economiche, politiche e sociali, mantenendo la sua posizione di leader nazionale nella gestione integrata delle infrastrutture.

Oggi ASPI è un player di eccellenza, attore di cambiamento e leader nell'offerta di servizi innovativi e infrastrutture, che gestisce 2858 Km di rete autostradale, circa il 50% dell'intera rete nazionale a pedaggio, distribuita in più di 15 regioni. Il gruppo, che ha conseguito ricavi operativi pari a 4.175 milioni di euro nel 2022, negli ultimi anni ha orientato i propri sforzi al miglioramento e all'espansione della rete, con un investimento totale di circa 21 miliardi di euro tra il 2020 e il 2038, per potenziare e ammodernare l'infrastruttura del Paese.

La leadership nel cambiamento è parte integrante del DNA del Gruppo. La storia di Autostrade è infatti sempre stata caratterizzata da un approccio pionieristico all'innovazione, e ha una profonda connessione con la storia ingegneristica del Paese, per il ruolo fondamentale svolto nell'evoluzione delle infrastrutture nazionali e il contributo allo sviluppo economico dell'Italia. La sua leadership ingegneristica si estende anche a progetti internazionali di innovazione autostradale, che hanno funzionato da leva per acquisire competenze avanzate e trasferire conoscenze ai progetti nazionali. Questo ha contribuito al potenziamento delle capacità tecniche e all'integrazione di soluzioni innovative, attingendo dalle migliori pratiche globali. L'eccellenza operativa di Autostrade è quindi il risultato di anni di esperienza e successi ingegneristici, che le hanno consentito di consolidare la sua posizione di guida nell'innovazione e di affermarsi come una delle principali imprese nel panorama infrastrutturale italiano.

2. Il contesto

2.1 Macro-scenario: il mercato della mobilità

L'industria della mobilità attraversa oggi un processo di profonda trasformazione. Le conseguenze a lungo termine della pandemia da COVID-19 unitamente alle twin transition del green e del digitale, stanno agendo come amplificatori del cambiamento ridefinendo non soltanto le abitudini e i comportamenti degli individui legati alla mobilità, ma anche i modelli di business prevalenti nel settore. È in questo contesto che emergono quattro driver del cambiamento della mobility industry.

*La **sicurezza stradale** è stata individuata tra le dieci aree di intervento della Commissione Europea nel 2020 all'interno della Strategia per la Mobilità Sostenibile e Intelligente con l'obiettivo "Vision Zero" che identifica come aree cruciali per lo sviluppo futuro della sicurezza stradale le infrastrutture sicure, i veicoli sicuri, la riduzione delle infrazioni e un intervento post-incidente tempestivo ed efficace. Per l'Italia la sicurezza stradale è ancora una sfida rilevante e strettamente legata alla crescente vulnerabilità del territorio italiano e all'obsolescenza delle infrastrutture di mobilità.*

*Segue il **digitale**, con la crescita del mercato degli Intelligent Transport Systems (ITS), che comprende servizi di gestione delle flotte e del trasporto pubblico, che accelera la trasformazione del settore. Per il 2022, si prevede un incremento globale degli investimenti nelle soluzioni digitali del 12% annuo che potranno raggiungere i \$50.23 miliardi nel 2027. In questo contesto, la realizzazione delle Smart Roads, basata su tecnologie come l'Internet of Things (IoT) e l'Intelligenza Artificiale (IA), assume un ruolo centrale, coinvolgendo infrastrutture stradali, ferroviarie e aeroportuali contribuendo a creare una mobilità intesa come ecosistema digitale.*

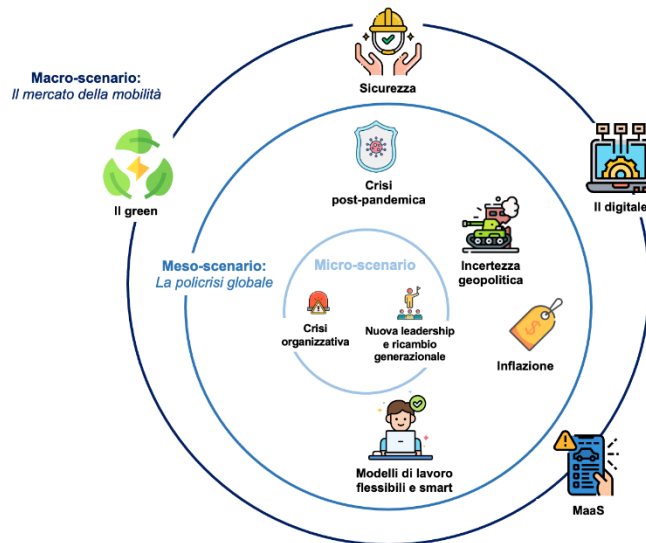

*Anche la **sostenibilità** assume particolare rilevanza per il futuro del settore della mobilità. Mentre nel 2022 il car-sharing ha registrato in Italia un aumento del 41%, con oltre 49 milioni di viaggi e un fatturato di 178 milioni di euro, le immatricolazioni full electric rappresentano meno del 4% del parco circolante, con circa 200.000 unità al 30 giugno 2023. Crescono gli impatti economici derivanti dai danni alle infrastrutture veicolari dovuti ai cambiamenti climatici, che potranno raggiungere i 5,17 miliardi di euro all'anno entro il 2050.*

*A livello europeo, il paradigma della **Mobility-as-a-Service (MaaS)** propone inoltre una mobilità più efficiente e sostenibile con l'ottimizzazione della relazione pubblico-privato, attraverso un accesso semplificato a opzioni di mobilità diverse e un focus sulle soluzioni sostenibili come lo sharing. Questo paradigma rappresenta un driver chiave nella trasformazione digitale della mobilità, incoraggiando la collaborazione tra enti pubblici e privati attraverso piattaforme digitali di intermediazione per diversificare l'offerta MaaS.*

2.2 Meso-scenario: l'interconnessione dei sistemi globali e la policrisi

Il cambiamento a livello meso richiama il concetto di policrisi, che indica l'interazione di diverse crisi provenienti da sistemi vari che, interagendo tra loro amplificano i loro effetti (Lawrence et al., 2022). La crescente interconnessione tra mercati e sistemi globali ha infatti aumentato i rischi sistemici per le organizzazioni, anche per quelle che operano nel settore della mobilità. Attualmente, i principali nodi delle poli-crisi globali sono le conseguenze a lungo termine della pandemia da COVID-19, le crisi geopolitiche e le tensioni inflazionistiche che hanno portato ad un ripensamento della mobilità in chiave sostenibile. Le sfide create da questi nodi problematici influenzano gli attori del mercato della mobilità nella gestione delle persone, nei modelli di lavoro e nelle aspettative individuali, spingendo le aziende del settore a modificare le proprie strutture in chiave collaborativa, per favorire il benessere e la crescita personale dei dipendenti.

Figura 1. I driver del cambiamento

2.3 Micro-scenario: elementi di discontinuità interni

ASPI si è confrontata con shock interni rilevanti. Il primo è il crollo del viadotto Polcevera (Ponte Morandi), avvenuto nell'agosto del 2018. Dopo l'evento, l'attenzione mediatica si è concentrata non solo sul disastroso evento, ma anche sulla gestione della infrastruttura da parte della Società e sulle mancanze nelle manutenzioni, con un acceso dibattito sull'opportunità del rinnovo della concessione. In questo contesto di crisi ASPI avvia un percorso di trasparente revisione delle proprie procedure, che si estende alle controllate e a tutte le funzioni interne e che coinvolge anche il modello organizzativo e la governance.

Nel 2021 Atlantia cede l'88,06% delle quote della Società Autostrade per l'Italia alla Holding Reti Autostradali S.p.A. (HRA), un veicolo di investimento formato da CDP Equity, Blackstone Infrastructure Partners e Macquarie Asset Management. La compagine azionaria di ASPI oggi è rappresentata oggi da CDP Equity e dai fondi gestiti da Blackstone e Macquarie oltre ad Appia Investment e Silk Road.

Figura 2. Azionariato e organigramma del Gruppo Autostrade per l'Italia

Fonte: ASPI

La crisi seguita al crollo del Ponte Morandi, ha condotto al cambio nella leadership di ASPI con l'arrivo del nuovo amministratore delegato Roberto Tomasi e il ricambio generazionale con la sostituzione di tutte le prime linee dell'organizzazione. È in questa fase che prende avvio la trasformazione organizzativa di ASPI:

Siamo partiti dalla convinzione di dover risolvere un elemento specifico che era quello della gestione dell'infrastruttura e progressivamente abbiamo iniziato ad allargare la nostra visione a 360 gradi. Ci siamo resi conto che dovevamo reimpostare l'azienda a tutto tondo senza lasciare nulla di intentato.”

- Roberto Tomasi, Amministratore Delegato, Autostrade per l'Italia

La roadmap verso il cambiamento viene formalizzata nel Piano Industriale ASPI 2020- 2023, articolato attraverso i pilastri del progetto Next (Figura 3), i quali definiscono le principali aree di intervento e le declinano in un'ottica operativa, con un approccio sistematico e graduale alla trasformazione.

Figura 3. I pilastri del Piano Strategico di Trasformazione.

3. Il nuovo baricentro strategico: velocità ed eccellenza operativa

Dal 2020 ASPI ha intrapreso un profondo percorso di rinnovamento interno, ridefinendo il suo orientamento strategico sulla base di due dimensioni: la **velocità** e l'**eccellenza operativa**. Questa trasformazione è stata volta a posizionare l'organizzazione al vertice del settore, attraverso una strategia corporate focalizzata su ricerca, innovazione e sostenibilità.

La velocità è diventata sinonimo di accelerazione creativa, consentendo ad ASPI di sviluppare un approccio integrato e agile al business, mentre l'eccellenza operativa si collega al passato del Gruppo, ancorando le decisioni strategiche all'innovazione, alla competenza ingegneristica e alle risorse infrastrutturali e alle competenze uniche. Questi due principi emergono come fattori chiave che guidano la strategia operativa del Gruppo, la cui nuova missione si propone di “rendere la mobilità più sostenibile, sicura, innovativa ed efficiente”.

ASPI adotta una nuova vision basata sulla centralità delle persone, includendo lavoratori, utenti, fornitori e comunità locali, riconoscendoli come elementi chiave nella creazione di valore e orientando l'organizzazione a promuovere la loro sicurezza, benessere e a svilupparne i talenti.

Nella sua vision ASPI sottolinea inoltre il ruolo dell'infrastruttura autostradale come “spina dorsale” dell'Italia, generando valore condiviso e contribuendo al benessere collettivo.

3.1 La ridefinizione dei valori e della cultura organizzativa

ASPI ha inoltre formalizzato i suoi **nuovi valori**, promuovendoli a principi guida dell'attività dell'organizzazione. Attraverso questa formalizzazione, l'azienda ha riconsiderato la propria identità culturale, utilizzando i valori come elemento unificante per connettere le persone e sviluppare una cultura organizzativa coesa, allineata con la sua vision e la sua mission. I valori nella trasformazione di ASPI rappresentano anche un elemento di rottura rispetto alla struttura precedente, che era caratterizzata da gerarchie rigide e dalla mancanza di comunicazione, diventando il fondamento di una visione condivisa all'interno del Gruppo come “comunità”:

“(…) non possiamo prescindere da due fattori. Da una parte ci sono i valori che permettono all'azienda di immaginare il proprio futuro remunerando i suoi investitori, dall'altra c'è la gestione di una infrastruttura di interesse pubblico che va ben oltre il ritorno aziendale”

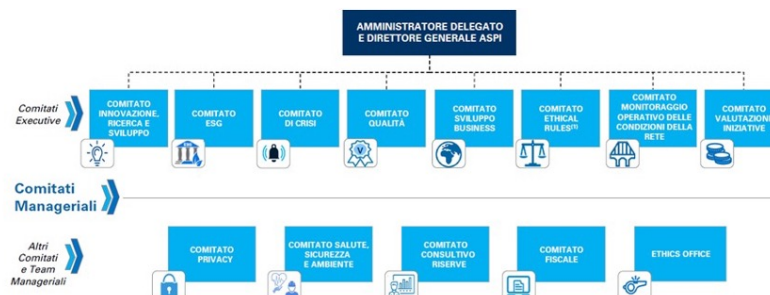

- Roberto Tomasi, Amministratore Delegato, Autostrade per l'Italia

I valori di ASPI mettono al centro l'**etica**, la quale diviene il motore dell'agire del Gruppo, e la **trasparenza** come l'elemento fondante di un approccio aperto al mercato, nei processi, nelle informazioni, nella chiarezza delle scelte strategiche e negli obiettivi che vengono condivisi a tutti i livelli. Tra i valori affermati da ASPI, assumono rilevanza anche la **sicurezza**, intesa da ASPI come la creazione di una condizione oggettiva di protezione che tuteli le persone nella fruizione delle infrastrutture e nel lavoro per le infrastrutture e, infine, la **responsabilizzazione** a tutti i livelli, una delle condizioni ritenute da ASPI come necessarie per integrare i valori sociali all'interno dell'organizzazione e fare in modo che si creino strutture permanenti per l'accrescimento della professionalità e dell'agire responsabile e sostenibile.

3.2 Un nuovo modello decisionale partecipativo

ASPI ha rivisto completamente il suo modello organizzativo seguendo una logica di struttura lineare, ridefinendo funzioni e ruoli sia a livello centrale che nelle divisioni di tronco. L'organigramma è stato reso accessibile a tutti i livelli, per facilitare una trasparente lettura delle funzioni e una maggiore conoscenza interna dei rapporti tra le strutture.

Figura 4. Struttura dei Comitati Manageriali.

Fonte: ASPI

La nuova struttura dell'organizzazione ha privilegiato la comunicazione orizzontale basata sui Comitati Manageriali che rappresentano le tredici aree ritenute chiave per lo sviluppo del business e la realizzazione della mission del gruppo. Questa struttura facilita la comunicazione trasparente delle informazioni, promuovendo la collaborazione tra funzioni corporate e controllate e creando un naturale approccio orizzontale nella definizione dei ruoli e delle decisioni. I Comitati Manageriali hanno permesso di superare la struttura gerarchica e a silos, favorendo maggiore autonomia tra le funzioni, garantendo al contempo un costante controllo e circolazione della conoscenza e dei dati.

3.3 Comunicazione e democratizzazione dei sistemi decisionali

I principi e valori della trasparenza e della responsabilizzazione delle persone e della centralità del dato sono stati i driver di un processo di istituzionalizzazione del dialogo tra funzioni interne alla corporate, e tra la corporate e le loro controllate, che ha condotto all'affermazione del "Dialogue for Company Values". Si tratta di una piattaforma di scambio e un luogo permanente di discussione, di raccordo e di problem solving interfunzionale che opera attraverso un set di meeting prestabiliti a cadenza settimanale o mensile, in cui vengono discussi aspetti strategici e operativi legati al business di ASPI.

Il Dialogue for Company Values funziona quindi da leva per aumentare l'efficacia dei processi informativi e decisionali e l'accountability interna mediante il coinvolgimento e la responsabilizzazione diretta dei singoli individui coinvolti nelle decisioni, con una circolazione continua delle informazioni e dei dati.

Figura 5. Finalità chiave del Dialogue for Company Values.

Fonte: ASPI

3.4 Il digitale come abilitatore: il valore del dato

La digitalizzazione ha rappresentato uno degli aspetti core del piano di trasformazione organizzativa di ASPI. Infatti lo sviluppo in chiave digitale del Gruppo si è uniformato ai principi stabiliti all'interno del piano "Next to Digital", che attribuisce una nuova centralità alla trasformazione digitale come parte integrante della nuova struttura organizzativa basata sulla trasparenza e la condivisione dei dati. Le attività di sviluppo della trasformazione digitale sono state organizzate su nove aree core, in coerenza con la vision ed i valori di ASPI. Tali aree si strutturano in Chapter attraverso cui viene gestita operativamente la trasformazione digitale. All'interno delle aree prioritarie sono stati inoltre individuati 60 use case. A ciò si affianca l'adozione di una modalità di lavoro agile che, attivata nel settore IT, è stata adottata dalle altre aree funzionali, ed è diventata di dominio comune in tutta ASPI. Oggi in azienda vengono gestite più di 40 room agile in parallelo con la partecipazione di circa 1.800 persone appartenenti a tutte le funzioni del Gruppo, includendo le Società controllate:

"Secondo me è stato molto rilevante, almeno per il buon esito del piano di trasformazione digitale, l'aver adottato un modello di lavoro agile, senza il quale oggettivamente ASPI non sarebbe riuscita a realizzare quello che ha fatto in tre anni."

– Danilo Gismondi, Direttore IT e Digital Transformation - Autostrade per l'Italia

Il risultato della digitalizzazione è stato il coordinamento e l'adattamento spontaneo delle funzioni dell'organizzazione mediante un flusso di informazioni trasparenti e accessibili.

In ASPI i dati non sono più appannaggio di una singola funzione o dell'area che li ha generati, ma sono immagazzinati in repository e vengono condivisi e resi pubblici.

I dati divengono inoltre attivatori del dialogo interno e collettivo che si svolge nell'ambito delle strutture create per gestire i processi di decision making in chiave collaborativa e informata, attraverso i Comitati Esecutivi e le strutture del Dialogue for Company Values:

"Da qualche anno abbiamo definito un indice di copertura digitale dei processi aziendali che si chiama Digital Coverage Index. Questo indice nel 2020 era sotto il 25%, ad inizio 2021 era di circa il 30%. Abbiamo chiuso l'anno 2023 con una copertura digitale media del 75%."

- Danilo Gismondi, Direttore IT e Digital Transformation, Autostrade per l'Italia

La trasformazione di ASPI ha quindi previsto l'adozione di un modello di decision-making guidato dai dati, utilizzando in tal modo le informazioni raccolte e condivise come guida per la presa delle decisioni a tutti i livelli: corporate, business e funzionale.

Oggi, l'organizzazione utilizza i dati per monitorare il mercato, prevedere andamenti e valutare le prestazioni in tempo reale. Questo gli consente di reagire dinamicamente alle sfide sistemiche e alle nuove tendenze della mobilità. La trasformazione data-driven è stata abilitata dal digitale, che ha creato connessioni significative tra persone e infrastrutture attraverso cinque principi chiave: centralità dei dati, sicurezza, velocità di esecuzione, connessione e trasparenza interna e infine ricerca.

ASPI ha valorizzato la trasparenza e l'importanza dei dati attraverso una ristrutturazione dei processi interni e la mappatura degli asset. Il progetto PWAY, si è incentrato sulla mappatura dei processi aziendali con un approccio di catena del valore e di standardizzazione. Ogni attività è stata dettagliatamente mappata attraverso flow diagram di input e output, seguendo una struttura gerarchica dal livello 0 al livello 3. Complessivamente, sono stati mappati 38 processi di livello 0, ciascuno associato a un owner e arricchito da ulteriori microprocessi al livello 3, portando a oltre 2300 flow diagram di processo. I dati sono facilmente accessibili all'interno dell'intranet aziendale tramite un repository interattivo, promuovendo la conoscenza diffusa dei processi e garantendo la continuità delle informazioni anche con il turnover aziendale.

Accanto alla mappatura dei processi, anche la mappatura degli asset è stata ritenuta strategica al fine di assicurare l'ottimizzazione delle attività di monitoraggio delle opere in concessione, il miglioramento della governance dei dati sugli asset e l'ottimizzazione dei processi di ispezione e di manutenzione degli stessi. Il processo di mappatura degli asset è stato realizzato attraverso la digitalizzazione degli stessi mediante Argo, una piattaforma digitale unica a livello europeo, basata su strumenti di Intelligenza Artificiale e sviluppata con il supporto di IBM e la controllata Movyon. Argo è un inventario digitale che raccoglie e gestisce i dati strutturali di ponti, cavalcavia, viadotti e gallerie, e che in tal modo possono essere aggiornati in tempo reale. L'installazione di sensori IoT consente inoltre di raccogliere dati sullo stato di salute delle opere mappate. Il building information modeling, che viene creato partendo dai dati del database, consente inoltre di supportare l'operatore nella fase ispettiva. Mediante le tecnologie di geo-referenziazione è possibile inoltre effettuare scansioni tridimensionali dell'opera, mentre l'integrazione dell'Artificial Intelligence affianca l'operatore nell'analisi puntuale delle fotografie dei droni e nell'approfondimento degli aspetti che attengono l'identificazione puntuale dei difetti associati ai componenti dell'infrastruttura.

3.5 Il valore delle persone: coinvolgimento, benessere

L'aver incluso le persone e il loro valore nella vision dell'organizzazione diventa il pivot che orienta il reframing organizzativo di ASPI alla centralità delle iniziative che sono volte alla valorizzazione del benessere organizzativo a tutti i livelli, mediante l'istituzionalizzazione della inclusività e della diversity. La valorizzazione della diversità e dell'inclusione all'interno dell'organizzazione si avvale del contributo dell'Employee Resource Groups (ERG), un team interno ad ASPI ad appartenenza volontaria attivo nella promozione di iniziative e progetti inclusivi con idee e competenze specifiche.

Le iniziative per l'accrescimento del benessere organizzativo hanno inoltre previsto una sistematizzazione del ricorso allo smart working. L'accordo sulla flessibilità firmato da ASPI ha dato una forte spinta il lavoro da remoto, per corrispondere ad un triplice obiettivo organizzativo:

- *aumentare la produttività aziendale;*
- *favorire la conciliazione famiglia-lavoro;*
- *ridurre l'impatto sull'ambiente.*

Nel percorso di valorizzazione delle persone, il nuovo modello organizzativo di ASPI ha inoltre previsto la creazione di istituzioni interne volte a promuovere l'attivazione e la partecipazione dei dipendenti nella comunità mediante il modello delle Communities, concepite come organismi che hanno il ruolo di reti di connessione con il mondo esterno all'organizzazione, per la condivisione sul territorio e con le comunità locali dell'expertise e dei valori del Gruppo.

3.6 Leadership generation: talent nurture e attraction

La vision umano-centrica di ASPI ha guidato l'implementazione di un nuovo framework di talent attraction e nurture, focalizzato sulla multidimensionalità. Questo approccio si basa sull'attrazione di nuovi talenti mediante relazioni solide con enti formativi esterni e sull'investimento nell'up-skilling e re-skilling delle risorse interne. I programmi dedicati agli "Alti Potenziali", identificati come le risorse di talento che mostrano elevate performance e alto potenziale, promuovono la crescita attraverso percorsi dedicati di induction, formazione manageriale, coaching e "Shadow Management". Questi programmi consentono il costante allineamento della leadership ai valori dell'organizzazione e favoriscono il training on the job per lo sviluppo delle capacità di guida dei manager di domani.

3.7 Il valore della sostenibilità

La mobilità sostenibile è identificata come un elemento distintivo della mission del Gruppo e rappresenta uno dei pilastri del Piano Trasformativo ASPI, che segue il mega-trend del green. ASPI ha fissato obiettivi strategici basati sull'integrazione nella propria strategia di business dei pilastri ESG (Environmental, Social, Governance), legandoli al programma di trasformazione NEXT. Questo orientamento strategico guida una transizione verso l'infrastruttura connessa e digitale che abilita la mobilità sostenibile del futuro:

"Noi siamo andati verso una direzione diversa e quindi abbiamo reso la sostenibilità un asse strategico della nostra missione. Peraltro, questo si sposava benissimo già con la mission e la vision che proprio in quel momento venivano definite: ASPI come operatore della mobilità sostenibile, efficiente, all'avanguardia."

- Concetta Testa, Head of Sustainability, Autostrade per l'Italia

La strategia ESG di ASPI ha già permesso di ottenere significativi Rating ESG da parte di agenzie riconosciute a livello internazionale (e.g. Moody's - ESG Solutions, CDP - Disclosure Insight Actions) e una prima evidente prova dell'impegno dell'azienda di integrare le questioni ambientali e sociali nella propria strategia di sviluppo e nella propria struttura di governance sono le emissioni obbligazionarie sostenibili, collocate dall'inizio del 2023 per un valore complessivo di circa un miliardo e mezzo.

3.8 Il reframing del network esterno

La forte capacità di innovazione tecnologica di ASPI si manifesta attraverso collaborazioni con società controllate che consente di creare una rete di risorse e competenze interne distintive ed integrate. Questa rete solida è fondamentale per lo sviluppo del business e la realizzazione di soluzioni digitali per migliorare la velocità e l'eccellenza operativa, ottimizzando al contempo i processi interni.

L'orientamento aperto all'innovazione si riflette tuttavia anche nelle molteplici collaborazioni con enti di ricerca, istituzioni e altre imprese del settore. La logica che presiede all'innovazione è quella di esplorazione continua e che permette ad ASPI di riconoscere idee, trasformarle in sperimentazioni e convertire i risultati della ricerca in valore condiviso, integrando costantemente le innovazioni nel proprio business.

L'organizzazione è inoltre attenta alle innovazioni sviluppate da parte di startup e alla valorizzazione dei progetti e delle idee da parte di ricercatori, supportando in tal modo i processi di trasferimento tecnologico:

"Il Gruppo ASPI ha l'ambizione di partecipare da protagonista alla rivoluzione della mobilità sostenibile che sta interessando il trasporto. Una sfida in cui lo scambio con università ed enti di ricerca e la partecipazione ad eventi e

convegni dedicati sono diventati elementi più centrali nel percorso di trasformazione intrapreso. Abbiamo partnership con realtà nazionali europee che raccolgono le diverse concessionarie autostradali e/o operatori del settore. La partecipazione a convegni e seminari ci stimola a immaginare e trovare soluzioni, che possono essere implementate e ci spingono a pensare a nuove idee, che oggi condividiamo al nostro interno molto più che in passato.”

- Gianluigi Iacobone, Direttore Ufficio Studi e Strategie, Autostrade per l'Italia

Cosa apprendiamo. Un modello organizzativo agile come equilibrio nel paradosso

Il caso ha analizzato gli elementi costitutivi della trasformazione di ASPI, identificando i **principali motori del cambiamento**, i **driver della trasformazione** e le **attività di reframing** che sono state poste in atto per realizzare il cambiamento organizzativo.

La rapida evoluzione dello scenario di riferimento, guidata da un lato dall'evoluzione delle tecnologie digitali disruptive, con la conseguente trasformazione del mercato della mobilità, e dall'altra dalla crescente attenzione alla sostenibilità ed alla sicurezza come nodi centrali nel futuro dalle gestione delle infrastrutture, hanno rappresentato, insieme agli elementi del meso e del micro-scenario, dei fattori di innesco della trasformazione che ha rivoluzionato il modello organizzativo di ASPI in chiave agile.

Infatti, l'esigenza di rispondere attivamente al dinamismo del contesto esterno, con velocità, agilità strategica, e al contempo di effettuare immediati interventi correttivi e di early warning per prevenire eventi fatali e correggere le inefficienze del passato, valorizzando i principi di qualità, sicurezza, eccellenza operativa, sono stati driver di revisione delle strutture organizzative del gruppo a 360°.

Si tratta di un processo che ha coinvolto l'organizzazione a tutti i livelli, sia la corporate che le sue controllate, e che ha permesso di considerare il cambiamento come parte integrante della nuova vision del Gruppo.

Il caso mostra come la trasformazione in chiave agile di ASPI fa leva su tre dimensioni fondamentali di cambiamento che sono: le risorse chiave (gli asset infrastrutturali), i Dati (abilitati dal digitale) e le Persone (il talento e le comunità). Queste tre dimensioni sono state interpretate dall'organizzazione come tre risorse dinamiche capaci di conferire all'organizzazione agilità strategica, potenziandole quindi la capacità di cogliere le opportunità in mercati in rapido sviluppo (McCann, 2004), di percepire i cambiamenti esterni e di adattarsi con velocità (Braunscheidel & Suresh, 2009). Tali dimensioni sono connesse e sono alla base della creazione di una organizzazione capace di raggiungere equilibri dinamici anche in condizioni esterne incerte, guidate dalle twin transition e dalle global policrisis.

Il collante tra questi tre building blocks dell'agility è rappresentato dai valori e dalla vision dell'organizzazione, i quali divengono la guida dei processi decisionali e di gestione degli asset e delle risorse, ponendo le basi per la creazione di un'impresa non solo responsabile ma anche partecipativa e partecipata, intesa come comunità di principi e di valori e orientata al benessere della collettività.

Figura 6. I building blocks della trasformazione organizzativa al tempo delle paradoxical tensions.

La centralità dell'etica dell'agire organizzativo pone inoltre le basi per costruire una nuova relazione nei confronti degli stakeholder e degli azionisti basata sulla responsabilità (Goel e Ramanathan, 2014), con un codice di condotta istituzionalizzato per l'organizzazione che è il punto di orientamento per la costruzione di un player di mobilità capace di essere attore di innovazione responsabile nel settore, pur mantenendo il legame con le proprie tradizioni e con la propria comunità.

Il principio dell'eccellenza operativa valorizza l'heritage del gruppo fondata su competenze ingegneristiche inimitabili, le quali rappresentano la fonte di capacità dinamiche nel mercato presente e nell'industria della mobilità di domani.

Inoltre, il tragico evento del ponte Morandi, la crisi organizzativa che ne è seguita e il cambiamento della leadership hanno dato insieme avvio ad un percorso di riflessione profonda a tutti i livelli, generando un ground zero organizzativo che ha rappresentato il punto di partenza nella ricostruzione dei significati dell'organizzazione, dei suoi valori, del senso da attribuire al passato e alla proiezione futura del Gruppo.

Questi fattori di crisi interna hanno creato l'opportunità di implementare cambiamenti positivi, alimentando la readiness dell'organizzazione e potenziando la sua capacità di adattamento e la sua agilità strategica. In ciò il caso dimostra anche come le crisi organizzative, se gestite in modo cooperativo e risolutivo anziché focalizzarsi solo su colpe e responsabilità, possono diventare un'opportunità per rinnovare il purpose dell'organizzazione e avviare processi di trasformazione in chiave agile.

Happiness and emotions at work in organizational relationships. The role of affectivity and empathy for meta-organizational and non-hierarchical solutions in the resilient firm

LUCIANO PILOTTI¹

Abstract

Creative and intelligent organizations (private and public) have the task of offering favorable and welcoming contexts, enabling and facilitating meaningful relationships between people with their collaboration and cooperation, placing them at the center of their action for a continuous improvement of the corporate climate. This happens for ethical reasons, but also because this improves creativity and performance, reducing the cost of conflicts and absenteeism and increasing relational potential also as a source of increased cognitive productivity and meaning, therefore of cohesion. More participatory and non-profit maximizing but resilience-oriented organizations to improve the ability to adapt in complex worlds to push the convergence of the double ecological and digital transition. Among the most underestimated levers of transformation we find the qualities of human capital and relationships between people as sources of shared creation of value through the mobilization of emotional intelligence (catalyst of 4 other integrated intelligences - analytical, practical, creative and social) and dynamics capabilities for increasingly open, inter-disciplinary and inter-functional roles. The objective of this work is to illustrate these emerging processes of organizational change for greater inclusiveness and cohesion for more participatory business models that lead towards greater job satisfaction and therefore also towards states of greater shared happiness.

Key words: *Happyness, emotions, post rationality, human-social capital, 4 integrated intelligence, organizational change*

Framing of the research. *The research paper focusing in the first part the transformation of organization over crisis of Fordism and hierarchical model of organization of labor facing the complexities of the world as interdependencies between digitalization, servitisation, sustainability and grouping competences. In the second part we explore the factor of post rationality following the seminal work of H.Simon until more recent work of Norman, Fineman or Rizzolati on neuroscience and mindfulness. The third part of the paper develop the organizational interconnections between 5 types of intelligence: practical, analytic, creative, emotional, social as a tool to build a grouping intelligence able to support a more large responsibility of every person and group. The forth part of the paper develop the connections between emotional intelligence and sensemaking as hyper-competence clue of politics coalition of organizational process towards a new social architecture of organization overcome hierarchy for a better and large participation of human resources to define strategy as an ecology of value in sharing knowledge and developing dynamic capabilities over traditional specialization of work. Realizing in that perspective a good level of happiness of people in organization and consequently a good level of resiliency for the growth in the long run.*

Purpose of the paper. *The purpose of the paper is to demonstrate the relevance of emotional intelligence in organizational eco-system as a key of adaptation able to improve concept of efficiency with a mixture of competences and virtues transforming the nature of leadership in coaching for new social mix of firm culture and best practice reinforcing participation, inclusion and gender pluralism reaching a diffuse spreading of happiness in organization.*

The path to spreading happiness at work is - for the things said above - a complex and medium-long term process that is intertwined with the construction of a happy job. Starting from generating a purpose and creating around it friendships, proximity and enthusiasm aimed at sustaining a hopeful outlook on the future. One of the key vehicles for organizationally achieving these objectives is the arborescent construction of a (micro) reference group where the trust-recognition in the potentials and the positivity necessary for medium-long term valorisation can blossom, through an initial sharing of purposes, norms and vision, with which to look positively at a horizon of meaning before us. A group where they receive the necessary recognition of their objectives and the results achieved and where respect for oneself (and others) in a relationship between equals is the fundamental enabling and triggering resource for meaningful and meaningful work, intelligent as well as useful, also as a discriminating barrier towards "negative" behaviors and cultures. Key to mobilization, training and maintenance of semantic capital intertwined with the quality of human and social capital

¹ University of Milano
e-mail: luciano.pilotti@unimi.it

in networks (Butera, 1990). For this reason, a generically understood friendship or a widespread yet equidistant and cold provision of empathy is not enough, but to achieve personal and corporate objectives together it is necessary to actively build "groupness":

- a - commit to maintaining the quality of the group atmosphere;
- b - develop the identification of common goals and a shared vision;
- c - formulate rules capable of facilitating the emergence of all the emotional potentials of the group members;
and - safeguard "group diversity" by encouraging inclusion and avoiding excessively exclusive or prejudicial behavior;
- f - create supportive, lively, engaging, fun, welcoming and relaxed environments.

A process that is an integral part of the construction of an expanded, shared and inclusive corporate culture of which our way of thinking and experiencing emotions are constitutive, putting our potential and that of the group to work, bringing out all possible talents, blazing a path to happy work, spreading happiness. They are the most open to new, creative, adaptable, collaborative, resilient and inclusive corporate cultures.

Of course, not all corporate cultures allow this path towards a piece of happiness to be achieved without suffering and effort and therefore producing unhappiness. The major obstacles are found in:

- i - excess pressure for short-term results;
- ii - excessive hierarchical pressure against dissent;
- iii - excess pressure from competitive antagonism;
- iv - excessive verbal redundancy without values and facts;
- v - lack of clarity on vision;
- vi - lack of respect;
- vii - absence of appreciation;
- ix - excessive pessimism;
- x - excesses of intolerance;
- xi - absence of equity and justice;
- xii - absence of balanced meritocracy.

A set of conditions that emotionally create distrust, fear, cynicism, anger, enormous waste of time, energy and talents and therefore with widespread outcomes of unhappiness which often translate into absenteeism, renunciation of participation, closure. In the long run, they generate conflict, detachment and rupture with exit solutions to overcome suffering, injustice and, sometimes, even behavioral damage.

Instead, we need emotional prosperity, in sharing and inclusion, developing integrity, justice, equity, valuing differences as a contribution to creativity, not separated from compassion and humanity in treatment. Because this is the way to ensure the right to growth and personal development of the individual, in the valorization of all the virtues and fundamental values (such as honesty, gratitude, indulgence, wisdom, affection) consistently with the growth of a shared vision of organization for superior profitability coupled with man's higher purposes towards a more just society. Therefore, skills and competences are not enough if not accompanied by virtues that effective HR must know how to investigate and enhance.

Methodology. Methodology of the work is focused on different case studies and secondary data for longitudinal analysis of organization in different cultural contexts (USA, European and Asian context) about the nature of leadership and transformation of it all over the world.

Results. Main results confirm the convergence between transformation of organization and convergence of individuation and cohesion principles overcome hierarchy model toward a flat model of situated context of relational capital in coordination process of chain of situated actions with cooperative labor multi-competence, reciprocal coordination and cognitive division of labor.

Friendship is the most formidable vehicle for strengthening meaningful and meaningful relationships, that is, a way to select and choose them in conditions of trust, sincerity and authenticity. For there to be friendship, authenticity and trust we must immerse ourselves in the recognition of the Other in order to be recognized and considered in turn. To offer the best of ourselves we must primarily feel part of a group from which we have sincere stimuli for improvement and into which we pour our trust and commitment. So there is a sociality (wide or narrow) in which we can immerse ourselves to feel part of a team, a team, a common adventure or project. In these conditions, the sense of belonging and esprit de corps are united with affectivity as the "erotic" glue of our relationships without remaining - possibly - prisoners of univocal and unilateral obsessions and passions. It is widely demonstrated that "good relationships" produce "good results" and this applies at work as in family or friendship relationships. But it is clear that this does not exist in nature, but requires our exploratory commitment and our availability to build (or reconstruct) empathic tissues by acting with sincerity, transparency and hospitality, starting from the assumption that we must live much of our time together with others in the company (as in the community or family) and we must make sure that we live it to the fullest and in a sensible and meaningful way, first and foremost by learning to welcome, understand and listen. But also learning to give up pieces of ourselves to the Other with whom we share work, tasks, projects, time, not fearing the expression or emergence of affectivity between emotions and conscience. In short, demonstrating empathy and that we are available to care for and care about the Other and not simply that "you are or are useful to you". It is clear that the emergence of self-interested behavior in relationships produces detachment and suspicion and every person in the company (or outside, in the

community or in the family) who does not feel respected or, worse, ignored, will withdraw in a defensive way. adopting strategies or actions of detachment or disinterest. In the company, what is needed instead is trust and understanding, to spread an environmental climate conducive to mutual concern, always aiming for high ethical values in transparency, which are even more relevant in moments of crisis and conflict. It then becomes fundamental for the company to communicate well and place itself in a position to receive answers, comments and reactions, opening itself up to their active understanding, both individually and collectively.

Here we need to put our emotional intelligence (EI) to work, as the engine of a cognitive and relational commitment to the construction of a meaning to our existence in that work and organizational context. Even highlighting incompatibilities or inconsistencies, as long as they are motivated and analyzed in depth, accompanying us to a conscious and responsible choice, without resentment or vindictive warnings often deriving from excessive personalization. Friendship at work is a glue for healthy relationships at work both for having fun and also for calmly dealing with crisis and conflict situations. The company that promotes friendship at work (as well as love) will also be a successful company.

Research limitations. The main limitation of work is empirical validation of main results that should be developed better with a more large longitudinal data in many countries, comparing different liberal democratic national contexts and possibly in a second step also with a comparison in a non liberal context (Cina for example).

Managerial implications. We can underline main managerial implications about the transformation of organization and different standard of efficiency comparing mechanical with biological perimeter of these in front of change in the complexity of the world.

Many investigations seem to point out the relevance of mobilizing emotional intelligence coupled with meaningful leadership (which approximates coaching) or - better yet - shared employeeship. Finally, that there is an underlying happiness that links what happens at work and what happens in private, domestic and family settings. In fact, we can reasonably expect that a happy worker or manager will be more motivated and involved, therefore more productive and creative, if they can be so in both areas of life with a more sustainable work-life balance and which companies try to achieve with welfare which in Italy still remains too "lukewarm" and limited to medium-large companies. In short, taking seriously the idea of happiness at work that mobilizes positive emotions, producing value for the individual as well as for the company (and for the environment), even if not always immediately recorded in consolidated financial statements, but certainly generating value in the medium-long term as appears to emerge from various empirical investigations (including Italian ones) on absenteeism, corporate welfare and smart working.

Overall, corporate investigations on the topic of corporate welfare, smart working and smart organization seem to converge on the idea that to enhance "happiness at work" we need to connect in a shared fabric of languages of collaboration and cooperation, the chain of connections between positive emotions, intrinsic motivations and commitment which are the foundation of semantic capital within more participatory organizational models even "beyond" the German model of *Mitbestimmung*, crossing the thread of the following dimensions in the production of meaning :

- Hope
- Scope
- Friendship
- Empathy
- Affectivity
- Sense

A purpose or meaning must be found within ourselves, first of all by selecting the activities to which we attribute the most value and which serve us to understand whether the organization we have chosen has the actual and/or only potential characteristics to offer the best conditions for this to happen. future and how much we can contribute to it. Therefore, without waiting for there to always be a sort of "invisible hand" that creates those useful Olympic conditions, because this will never happen without our active contribution. Our contribution is as important as the pre-existing conditions in which to operate and change ourselves and the organization itself. Our values then become an active part and not separated from the company objectives, because they are never extraneous to the workplace.

Have a purpose well defined and shared is then a relevant lighthouse to look at to signal the way forward, which strengthens us and makes us more resilient in the face of shocks. Because this allows us to better discriminate what is satisfactory from what is not by establishing in an ordinal way a system of objectives that are both subjective and organizational.

Originality of the paper. The main originality of the paper is an alternative use of a different field of organizational science in a mix with psychology and neuroscience developed in the last book.

We can see main impact by integrating plural corporate cultures in osmotic forms with multiple jobs that turn into skills and competences (but also interconnected virtues) and which we now list without any pretense of exhaustiveness:

- a - sensitivity to different bases of organizational and digital cultures;
- b - ability to innovate both in skills and un-skills areas;
- c - enabling the adoption of continuous connective learning strategies;
- d - stimuli towards multiple two-way communication skills;
- and - hybridizing co-creation of knowledge and focal solutions towards interdisciplinarity and inter-functionality;
- f - speed of ideation and prototype testing;
- g - ability to contaminate group openness - exchange - collaboration;

h - ability to influence and transfer, inspire and engage people;

i - multiple skills and competences in listening and active dialogue;

l - development of self-awareness and redefinition of command figures "beyond" control towards self-organization.

Abilities and skills which - not separated from virtues - enable meta-organisational solutions which decompose the traditional hierarchical structure (of the Weberian style applied by Fordism) capable of intercepting, speeding up and governing change management trajectories also in terms of de-hierarchisation and reticularisation (of people, groups, functions):

I - transversal communities of experts capable of contaminating traditional corporate culture, in particular - for example - in Big Data, IoT, Cybersecurity, AI, deep learning;

II - activation of cross-functional committees to guide systems of project objectives;

III - definition of "end-to-end" responsibilities of strategic processes;

IV - activation of DevOps, Agile, Lean organization methodologies ;

V - mixed multi-channel dynamic training formulas (unstructured frontal classroom, flipped classroom, synchronous and a-synchronous multidevices, theatrical and simulation workshops);

VI - mobilization of people's energies for the creation of meaning, with inter-generational exchanges, idea-sharing and contests, with prizes and recognition

The reasons for the effectiveness and efficiency of these solutions and approaches are now evident and confirmed by multiple investigations because we are looking for business contexts where we can first of all be satisfied and, possibly, even happy. Without fearing this last category, we must set ourselves the objective - already implemented by many companies - of bringing together the individual prosperity of people with the corporate-organizational and environmental prosperity as well as that of the communities they belong to through second-level welfare plans. By adopting suitable tools for co-generation of potential with a contractual regulation that accompanies - both workers and the company - a reasonable and sustainable compromise between motivation, reward, life (and professional) trajectory and climate (internal) with significant effects on the community territorial reference (external).

But what ensures lasting and robust satisfaction at work and in organizations? What type of intelligence needs to be mobilized? Which leadership is compatible with this underlying objective that links individuals to the company in the medium-long term along with life career strategies and not simple ones? How much does this influence the relationships between the company and the territories in which it is inserted in relation, for example, to its own identity?

Starting from the consideration that we spend two thirds of our life time at work (whether direct or indirect) this is reasonable to be spent well and in well-being (physical, cognitive, emotional), in a meaningful and meaningful way, in which to rediscover one's efforts and the commitment made as an expectation of meaning. Above all to connect responsible medium-long term choices to the short and everyday which is not always possible or easy to separate - except with behavioral refractions that undermine our balance and the serenity of our condition - useful for maintaining clarity in understanding what surrounds us and the relational and organizational dynamics. Because if primary needs can be ordered in some hierarchical form, for motivational needs an emotional-sentimental (or empathetic) balance is needed first and foremost because there is no simple orderability and because they fluctuate in time and space. That balance serves us to decide responsibly and not impulsively, not hastily, taking into account the context in which we find ourselves and looking at the possible consequences of our actions and their sustainability in space-time.

For all this we need Emotional Intelligence (EI) between the ability to listen, understand and act in the construction of a meaningful relationship, that is, one that goes beyond the immediate and that knows how to dynamically align choices at work and at work with private choices outside work, friends and family. Where simple extrinsic motivation or salary is no longer sufficient to retain workers (or attract new ones) given the wave of (voluntary) resignations in the last three years - in Italy, in Europe and in the world - where according to Gallup surveys (2023) there is an average of 75% of the working population dissatisfied with their work and/or the working environment. The causes of the Great Resignation derive from the search for well-being "without adjectives", that is, for some approximation of possible happiness, as a process that is never finished but always accessible and distant from any form of performance optimization to maximize remuneration.

The shortage of skilled personnel in the transition from Industry 4.0 to Industry 5.0: Impacts and challenges in the machine tool industry

ELEONORA BIGLIA¹ MONICA CUGNO² REBECCA CASTAGNOLI³

Abstract

In a context of transition from Industry 4.0 to Industry 5.0, there is a change of approach, from techno-centric to value-centric, with effects on the figure of Operator 5.0. To date, literature doesn't address the issue of skills mismatch in high technological sectors. This study examines how these transitions impact skill mismatches in machine tool sector. Using a mixed-method approach, it analyzes data from 13.2% of Italian machine tool manufacturers and conducts qualitative interviews.

The study reveals that: 1) while Industry 4.0 technologies fail to alleviate shortage of technical-skilled personnel, there is a growing but unconscious adoption of Industry 5.0 principles; 2) The primary challenge lies in inadequate technical training from education system and a lack of dialogue with industry.

The paper suggests companies address recruitment challenges through targeted training programs and engage policymakers. This research contributes to European Union directives and advances Operator 5.0 theory in machine tool sector.

Key words: industry 5.0; industry 4.0; operator 5.0; mixed-method; computerized numerical control machine tools

Framing of the research. *In 2015, Rada coined the term 'Industry 5.0' (Bessa et al., 2023) to highlight the centrality of the environment and people in industrial processes. Later, in 2016, Keidanren introduces the concept of 'Society 5.0' (Aires Moreira et al., 2021), focusing on the balance between economic development and the mitigation of socio-environmental problems, considering technologies not only as profit-making tools, but also as means to improve the quality of life of citizens. In 2018, Østergaard, co-inventor of the UR cobots (Kaivo-Oja et al., 2020), emphasizes the advent of Industry 5.0 as the return of the human element in production, arguing that Industry 4.0 leads to the dissipation of human creativity and critical capabilities.*

The importance of the topic is reinforced in 2021, when the European Commission decides to publish the report 'Industry 5.0: Towards more sustainable, resilient and human-centric industry' (EU, 2021), which is part of major policy initiatives on industry and technology, such as the regulation on artificial intelligence and the Green Deal.

The Industry 5.0 paradigm does not present itself so much as a technological or technical revolution, but more as a cultural revolution, bringing operators and the environment back to the forefront of production processes; it is thus spoken of as a complementary process to digital transformation and completion of Industry 4.0. In defining the development model of Industry 5.0, the European Commission identifies three essential pillars (EU, 2020), which would guide the transition from Industry 4.0 to Industry 5.0: human-centricity, sustainability and resilience.

The 5.0 paradigm – which shifts the focus from a techno-centric approach (focused on technology and its ability to control and protect the environment) to a value-centric one (focused on the idea that technology must be used to adapt the production process to the needs of workers and economic, environmental and social sustainability) – increases issues already present with 4.0. In this context there is a need to reflect on the emerging figure of the Operator 5.0 (Romero et al., 2021) and to understand its distinctive characteristics. The Operator 5.0 or 'Resilient Operator 5.0', adds to the requirements of social sustainability and human-centricity already present with Operator 4.0 (Bernus et al., 2016), the requirement of resilience, to complete the concept of Industry 5.0. The vision of Resilient Operator 5.0 focuses on the one hand on the creation of 'self-resilience' for the workforce and on the other hand on 'system-resilience' for human-machine work systems, in a production mechanism in which human operators and machines cooperate to ensure the best possible functioning of the overall system. Self-resilience refers to the productivity of each worker within the production environment.

e-mail: eleonora.biglia@edu.unito.it

² University of Torino
e-mail: monica.cugno@unito.it

³ University of Torino
e-mail: rebecca.castagnoli@unito.it

However, although the concept of the Operator 5.0 was predominantly introduced in the engineering literature with the need to implement resilience, an interdisciplinary understanding of the 5.0 operating elements and competencies that consider both technical and social aspects is lacking to date, in view of a transition from Industry 4.0 to Industry 5.0 (Castagnoli et al., 2022).

In the manufacturing industry, a sector that is a pioneer in adopting 4.0 technologies (Büchi et al., 2020), and is facing the transition to Industry 5.0, the skill mismatch is a growing problem (Cugno et al., 2022). In Italy, out of 531,000 job hirings planned for September 2023, 48% remained unfilled, due to the gap between the skills of workers and those required by companies (Unioncamere/Anpal, 2023). What is more lacking are technical-specialized, particularly in the Italian manufacturing sector, where the computerized numerical control machine tool industry demands advanced expertise from operators and designers due to increasingly complex machinery.

While the transition from Industry 4.0 to Industry 5.0 represents a turning point for the Italian machine tool industry, it could exasperate the shortage of specialized personnel, as the integration of increasingly complex technologies requires more articulated and transversal skills (Ucimu, 2023). The study conducted by Ucimu emphasizes the predominant effect of technological transformation on human resources, particularly on operators working in close synergy with high-tech machinery. This scenario underlines the importance of acquiring specific technical skills not only for those who are responsible for designing the machinery, but also for operators who use it.

In this context, skills can be considered a lever of competitiveness for companies in the sector; the result is an accentuated enhancement of the human figure.

Purpose of the paper. The paper enters the research strand on the Operator 5.0 with an interdisciplinary perspective aimed at understanding the changes in the figure of the Operator 5.0 brought about by Industry 4.0 and Industry 5.0. For this reason, the paper investigates the following research question: How does the adoption of Industry 4.0 and Industry 5.0 affect the problem of the shortage of qualified personnel in the machine tool sector?

The hypothesis that technological implementation can reduce this problem is based on the idea that automation and the use of advanced technologies can increase production efficiency by reducing the need for human resources for certain activities. Indeed, automation has had a significant impact on unemployment in various sectors, reducing the demand for unskilled labor but increasing the demand for highly skilled workers (Castagnoli, 2023).

The aim is therefore to test the hypothesis that technological implementation can reduce the need for personnel and thus mitigate the problem of the lack of skilled workers in certain sectors.

Methodology. The article adopts a mixed-methodology, quantitative and qualitative. As far as the quantitative analysis is concerned, a survey was developed, addressed to population of 250 Italian companies associated with Ucimu-Sistemi per Produrre, covering over 70% of the made in Italy sector (Ucimu, 2023).

The survey is administered between July and September 2023, on a structural level, it comprises 18 questions, divided into four macro-sections: the first one is dedicated to general questions about the company, the second to questions on the company's degree of technological implementation on Industry 4.0, the third to questions on the degree of attention towards Industry 5.0 principles and the fourth to questions on the difficulty of finding personnel.

The first part aims at obtaining information regarding the responding company in the survey; it should be specified that some informations (such as the number of employees of the responding company) are obtained directly from Ucimu, which offers direct contacts and data of its member companies.

The second section of the survey aims at obtaining information on the degree of technological implementation of Industry 4.0, investigates which 4.0 technologies were used by companies and then verifies what is the level of difficulty encountered in their adoption, based on a Likert scale (from 1=little to 5=very much). The study wants to verify, again based on the previous Likert scale, how much the enabling technologies affect various aspects of the company, such as productivity, efficiency, time, worker safety, costs, etc. Finally, about the adoption of 4.0 enabling technologies, the survey asks whether jobs decrease as a result of their adoption.

The third section investigates the degree of Industry 5.0 development at company level. In the first analysis, the study verifies whether investments in circular solutions have been made within the responding company, asking to indicate which ones in case of an affirmative answer. Then, the responding companies indicate, based on the Likert scale set out above, the level of readiness of the responding company to make investments aimed at fulfilling the three founding principles of Industry 5.0, to probe the importance that companies give to these aspects. Finally, the last question of the second section, asks to indicate the difficulties expected concerning the implementation of the company values characterizing Industry 5.0.

In the fourth and final section of the survey, the focus shifts to staff recruitment challenges. It examines where and how staff are primarily sought, investigates the urgency of the lack of skilled technical personnel within respondent companies, and identifies the most-needed professional roles, to highlight the extent of the problem. Furthermore, it asks to specify which professional figure is most lacking and it explores the factors influencing the shortage and solicit solutions, including the potential effectiveness of technological implementation and increased automation in production processes.

The survey concludes by asking companies to indicate in which fields, as a result of technological implementation, more experienced workers are sought after and then asking them to specify in which field it is, on the other hand, more difficult to find competent workers.

To study the performance of the survey results, the study uses the software R, to lead three types of analysis, Principal Component Analysis (PCA), Correspondence Analysis (CA) and Multiple Correspondence Analysis (MCA), to simplify the understanding of the data.

The first PCA tests whether there is a correlation between two variables, namely the propensity to invest in circular solutions and the propensity to invest in business resilience, with a third variable, the cost of equipment.

The second PCA investigates the correlation between the propensity to invest in new technologies in production aimed at improving the working conditions of employees with possible man-machine interface problems and the cost of equipment.

The CA investigates the correlation between the 4.0 enabling technologies companies use with the fields in which the need for skilled personnel increases most because of the implementation of these technologies.

As a final analysis in R, the MCA tests the correlation between three different variables, namely the number of employees, the need or otherwise to find a solution to the problem of the lack of technical-skilled personnel and the 4.0 enabling technologies companies use.

The final analysis in R employs MCA to assess the correlation between three variables: employee numbers, the need to address the lack of technical-skilled personnel, and the utilization of Industry 4.0 technologies.

Qualitative analysis involves two semi-structured interviews to delve deeper into topics relevant to the Italian manufacturing sector. The interviews target one large and one smaller company to uncover differences in the challenges faced and approaches taken between large and small enterprises.

The first interviewed is the smallest one, with around 30 employees and located in the province of Como. Next, the largest one, with around 300 employees and located in the province of Varese, was interviewed.

The interviews are conducted online, dialoguing, in the case of the first company, directly with one of the owners and in the second case, with the HR managers and the production office manager.

The interview asks both companies to specify their motivations for investing in Industry 4.0 technologies and to explain the main difficulties they encounter in adopting these technologies. Next, the interview requests whether they considered the lack of skilled technical personnel to be more of a technical problem or more of a social problem and to explain how they try to counteract and mitigate the lack of personnel.

The interview ends with an in-depth discussion of Industry 5.0 topics (sustainability, resilience and human-centricity), through which possible future developments can be verified.

Results

Quantitative analysis results

The sample obtains 33 responding companies from the survey, out of a population of 250 (13.2%). It is important to specify that this sample reflects the characteristic of the Italian machine tool industry to be mainly concentrated in the Centre-North, in fact companies responding to the survey are mainly located in this area, specifically, 21 in Lombardy, 6 in Piedmont, 4 in Emilia-Romagna and 2 in Veneto.

Regarding the enabling technologies of Industry 4.0, those most used by the sample are cyber-security (57,6%), simulation (48,5%) and horizontal/vertical integration (36,4%). An encouraging figure is represented by the companies that do not use any of these technologies, i.e. only 3% of the sample.

The adoption of these technologies is complicated by two main factors: the lack of personnel, highlighted in 51.5% of responses with ratings between 4 and 5 on the Likert scale and the presence of inadequately trained operators, indicated in 27.3% of responses with ratings between 4 and 5 on the Likert scale.

However, such technologies improve certain production aspects, such as increasing product and process reliability (51.5% distributed between scores 4 and 5), as well as increasing customer satisfaction (45.5% distributed between scores 4 and 5). Anyhow, there is still a low increase in productivity (36.4% distributed between scores 4 and 5) and an even lower reduction in costs (30.3% distributed between scores 4 and 5).

Importantly, the use of these technologies does not lead to a reduction in jobs for almost the entire sample (96.9%).

The data shows a good level of attention towards the founding principles of Industry 5.0 (sustainability, resilience, human-centric); suffice it is to note that, as far as sustainability is concerned, 65% of the sample affirms that they make investments in circular solutions. Furthermore, 87.8% of the sample strongly supports the incorporation of new technologies to improve working conditions, 60% shows a positive inclination towards the adoption of circular models and energy efficiency, and 72.7% supports the willingness to make investments aimed at improving corporate resilience.

As far as the shortage of skilled technical personnel is concerned, it is a common problem in the Italian machine tool industry, with 75.8% of the sample considering it an urgent issue to be addressed. For 69.7% of the sample, inadequate practical training in high school is rather an impact on this problem, as is for 69.7% the lack of interest on the part of young people in the sector.

Interesting is the data concerning the increase in demand for operators because of technological implementation by the sample. Even though the field of mechatronics is still the one in which demand is greatest (81.8%), given the nature of the sector, there is an actual increase in demand for specialized figures in the fields of electronics (63.6%) and informatics (39.4%), which reflects the actual widespread use of technology. Despite, however, the increase in technology in production, most of the sample has great difficulty in finding specialized personnel in the fields characterizing the sector, namely mechanics (63.6%) and mechatronics (63.6%).

Furthermore, for 81.8% of the sample, increased automation in production processes cannot be a solution to the problem of the lack of skilled technical personnel.

The study presents now the results of the analysis carried out using the R statistical software.

The first PCA studies the correlation of two variables, namely propensity to invest in circular solutions and propensity to invest in business resilience, with a third variable, the cost of equipment.

Graph 1: PCA on circular economy, resilience, and equipment cost

CostoAttrez = cost of equipment
 EcCirc = propensity to invest in circular solutions
 Resilienza = propensity to invest in business resilience

The graph shows a negligible correlation between the propensity to invest in circular solutions and the cost of equipment and between the propensity to invest in business resilience and the cost of equipment. This finding is based on the observation of the almost right angle formed by the corresponding vectors. However, a positive association emerges between the first two variables, indicating the tendency of companies to invest in both areas. This close relationship is corroborated by the acute angle formed by the vectors, indicative of a more robust correlation. Furthermore, the model can explain the variation of variables, as demonstrated by their position close to the circumference, especially in the case of the vector relating to the cost of equipment.

The second PCA is aimed at investigating the correlation between the propensity to invest in new technologies to improve employee conditions, with possible man-machine interface problems and the cost of equipment.

Graph 2: PCA on investments in new technologies for employees, human-machine interface issues, and equipment cost

NewTecDip = propensity to invest in new technologies to improve employee conditions
 ProblInterfUM = man-machine interface problems
 Costoattrezzature = cost of equipment

The graph shows an almost zero correlation between the propensity to invest in new technologies to improve working conditions and the other two variables; in fact, the vectors form an almost right angle. Moreover, all variables are well explained by the model and show a high level of significance, given the high closeness of the three vectors to the circle.

The CA analyzes the correlation between the 4.0 technologies used by companies and the areas where there is a greater demand for skilled personnel because of the implementation of these technologies.

Graph 3: CA on enabling Industry 4.0 technologies used and fields where demand for personnel has increased the most

Companies that use simulation more, have a greater need for operators in the field of mechanics; companies that have implemented artificial intelligence, have a greater need for operators in the field of informatics. The field of mechatronics, on the other hand, is not close to any particular technology, in fact it is a useful skill for a variety of technologies. Additive manufacturing, finally, requires many skills in the field of electronics.

In addition, at the bottom right there is an outlier (None) that can be disregarded in the analysis; this is because, as there is only one individual who answers None, data can be considered not statistically significant.

The last type of analysis is an MCA, which aims to analyze the correlation between the number of employees of the companies, the need or not to solve the problem of the shortage of skilled technical personnel (Yes/No) and the 4.0 enabling technologies used. To facilitate the analysis, technologies data are grouped and simplified, as most companies use more than one. This is possible by naming all combinations of technologies used.

Graph 4: MCA on number of employees, presence or absence of the personnel shortage issue, and enabling Industry 4.0 technologies used

T1 = Simulation; T2 = Horizontal/vertical integration, simulation, cyber-security; T3 = IoT, cloud computing, cybersecurity; T4 = Additive manufacturing, simulation, cyber-security; T5 = Simulation, cloud computing; T6 = Simulation, IoT, cyber-security; T7 = Additive manufacturing, horizontal/vertical integration, IoT, cloud computing, cyber-security, big data, artificial intelligence; T8 = Horizontal/vertical integration, simulation, IoT, cloud computing, big data; T9 = Cloud computing, cyber-security, blockchain; T10 = None; T11 = Cyber-security; T12 = IoT, cyber-security; T13 = Simulation, IoT, big data; T14 = Cloud computing, artificial intelligence; T15 = Augmented reality, horizontal/vertical integration, simulation, cloud computing, cyber-security, big data; T16 = Horizontal/vertical integration, cloud computing, cyber-security; T17 = Additive manufacturing, cloud computing, cyber-security; T18 = Horizontal/vertical integration, simulation, IoT, cyber-security; T19 = Additive manufacturing, augmented reality, simulation, cyber-security; T20 = Additive manufacturing, IoT; T21 = IoT, cloud computing, cyber-security, big data, artificial intelligence; T22 = Horizontal/vertical integration; T23 = Artificial intelligence; T24 = Cyber-security, blockchain; T25 = Horizontal/vertical integration, simulation; T26 = Horizontal/vertical integration, cyber-security, big data; T27 = Horizontal/vertical integration, cyber-security; T28 = Horizontal/vertical integration, simulation, big data; T29 = Cyber-security, big data

There is a high concentration at Yes and little at No. This is a symptom of the fact that the use of technology can not solve the problem of the lack of skilled technical personnel; in fact, companies that massively use technology are in the vicinity of Yes.

Two additional graphs are presented to aid in comprehending the preceding graph: one presents the correlation between the answers Yes and No and the 4.0 technologies used, while the other shows the distribution of the number of employees of the companies in the sample. This clarifies the interpretation of the previous graph and avoids overlaps between the variables.

Graph 5: On the left, Graph 4 excludes employee numbers, while on the right, it omits the presence or absence of personnel shortages and the utilization of Industry 4.0 technologies

It is difficult to assume that there is a correlation between the number of employees and the perception of the shortage of qualified personnel as an imminent problem within companies; this is because the majority of companies answered Yes, regardless of the number of employees. However, while large companies are only represented among those who answered Yes, smaller companies are present among both those who answered Yes and those who answered No. This discrepancy could stem from a limited sample or from the tendency of Italian companies in machine tool sector to be predominantly small companies.

In summary, this MCA suggests that the adoption of the enabling technologies of Industry 4.0 does not significantly address the problem of the shortage of technical-skilled personnel.

Qualitative analysis results

The interviews conducted confirm many of the results of the survey.

First of all, both companies, which use 4.0 technologies, state that they invest in them to make production process more efficient.

Both companies identify the lack of specialized technical personnel as one the biggest problems in the sector and the use of technology, as well as the lack of operational training, and have repeatedly stressed the ineffectiveness of the Italian school system in preparing young profiles before they enter the labor market. In this regard, both are doubtful about the effective functioning of ITS and the school system in general, stating that they respond to this problem with in-house training. In addition, the lack of dialogue between companies and the institution emerges, which is, in most cases, almost completely absent, especially for smaller companies. In fact, the largest company claims to start collaborations, to reduce this dialogue gap, not only with ITS and with alternance training projects, but also with the Politecnico of Milan and Confindustria, offering additional training courses for interested students.

Both companies see an increased demand for more qualified personnel as a result of the implementation of technologies; the most difficult figures to find are IoT developers for the larger company and electronic technicians for the smaller one.

As far as corporate sustainability is concerned, both companies state that they make investments in energy efficiency; specifically, the larger company is starting an investment in photovoltaic panels, while the smaller company replaces its previous, outdated lighting system.

The larger company is available to discuss the other two 5.0 principles (resilience and human-centricity), demonstrating to realize their potential; it states that companies are beginning to understand that the heart of the company is the people who work there, and that conditions must therefore be created for every worker to feel comfortable within the work environment and with the technologies through which they work. The company also believes and affirms that this can generate strong benefits in terms of solid business resilience.

Discussions

The first observation that can be made is that there is still a low efficiency of technology utilization by the sector, since the productivity gains and cost reductions that should result from such investments are still low.

Important to specify, is that machine tool industry operates with increasingly technological machinery, but which requires extensive knowledge of the same; the operator and the machine must guarantee extremely high standards of precision and this makes the human contribution still fundamental (Angelopoulos et al., 2022). As a result, it is clearer to understand why jobs do not shrink after technological implementation, but how perhaps they adapt to new requirements.

As far as the topic of 5.0 is concerned, the paper outlined a situation that is, as can be expected, still poorly defined, as awareness of the paradigm within the industry is still low.

Despite this, a fair level of attention to the founding principles of the paradigm is observed; this lays the foundation for a possible future development of the paradigm within the field discussed here.

The result is that increased automation does not reduce the shortage of staff, but it can increase the need for preparation. At that point, the problem of under-prepared schools reoccurs and the need for in-house training continues.

Since the lack of specialized personnel is both a technical and a social problem, it is necessary to take action on several fronts; starting with improving education, increasing investments in automation and introducing an effective dual apprenticeship system, and ending with the introduction of work placement programs in schools, increasing facilities for introducing young people into the company and promoting technical-scientific university courses.

In conclusion, the shortage of skilled technical personnel is both technical and social. On the technical side, the absence of training institutions capable of adequately preparing young people and the implementation of the enabling technologies of Industry 4.0 are not definitive solutions to the problem, but rather accentuate the need for a more qualified workforce. On the social side, a real change in the attitude of young people towards technical professions emerges, accompanied by a lack of promotion of the sector by institutions. This leads to a limited knowledge of the real potential of the sector and, consequently, to a reduced availability of skilled personnel for professions that will be increasingly rare.

As far as the 5.0 paradigm is concerned, it is still almost completely unknown at the entrepreneurial level; however, there is a growing, albeit still unconscious, interest in the founding principles of Industry 5.0 (sustainability, resilience, human-centricity), synonymous with potential positive developments within the industry.

Research limitations. *The document has some limitations that make further analysis of the topics discussed here necessary.*

Firstly, the limitation related to the emerging Industry 5.0 paradigm should be highlighted; this new industrial approach, being still in its embryonic stage, is reflected in the limited availability of studies and the scarcity of consolidated literature on it.

A second aspect is the choice to focus the survey exclusively on the Italian machine tool sector; this restriction has the consequence of obtaining data that are only concentrated in the central and northern regions. Therefore, the results obtained may not fully reflect the complexity and dynamics of the Italian industrial scenery in the context of the transition from Industry 4.0 to 5.0. Future studies could deepen this issue through analyses conducted on different geographical areas.

Furthermore, mention must be made of the limitation resulting from the decision to focus the study exclusively on Ucimu member companies; this choice leads to a reduction in the variety of the sample. This reduced sample may not be representative of the entire population of companies belonging to the Italian machine tool sector, thus compromising the generalizability of the results obtained.

Managerial implications. *The first managerial implication of the following elaboration is that of the identification of recruitment challenges; companies need to be aware of the underlying causes of the difficulties in identifying and recruiting technical-skilled workers, to make decisions aimed at problem mitigation.*

The second implication is the identification of the development of targeted training programs as the way forward in reducing the problem; companies must invest in specific, targeted training programs to close the skills gap. Such programs must be designed to provide the necessary skills to meet the challenges of the transition from Industry 4.0 to Industry 5.0.

A further implication concerns the involvement of policymakers; companies must actively collaborate with them to influence policies and incentives that support industry transition. This implies being able to clearly communicate the industry's needs and provide input on training programs and industry development policies.

Originality of the paper. *The following study is distinguished by its relevance to the demands and directives of the European Union. In particular, it focuses on the concept of Operator 5.0, identified as the core of the production system, following the mandate of the European Union that identifies it as a priority, to ensure the sustainable competitiveness of enterprises. This approach is not merely an adaptation of existing guidelines, but represents a new perspective that focuses on the well-being of people (SDG 3 – UN, 2015), the promotion of decent work (SDG 8), the stimulation of business innovation (SDG 9), the reduction of inequalities (SDG 10) and the promotion of responsible consumption and production practices (SDG 12).*

In parallel, the paper recognizes and emphasizes the need to adopt an interdisciplinary approach to address the cultural change inherent in the transition to Industry 5.0. This is not only a pragmatic approach, but represents a

conceptual innovation that recognizes the complexity of the problems and the need for integrated solutions that transcend traditional sectoral boundaries.

Through an approach that combines quantitative and interdisciplinary elements, the study contributes to the development of theory regarding Operator 5.0 within the machine tool sector, a particularly relevant environment for the Italian market.

Additive manufacturing: tecnologie umane e sostenibili per il benessere degli individui e della società

GIUSEPPE BONGIORNO¹ MARIACARMELA PASSARELLI² MICHELA SANGUEDOLCE³
LUIGINO FILICE⁴ ALFIO CARIOLA⁵

Abstract

Gli sviluppi tecnologici trasformano la società partendo dalle attività quotidiane. Negli ultimi anni sono state condotte numerose ricerche con l'obiettivo di innovare gli impianti medici utilizzati per la rigenerazione ossea e la guarigione dei tessuti corporei o più in generale per migliorare il benessere spinto anche dall'invecchiamento della popolazione. Questo lavoro esplora come nuove tecnologie afferenti all'additive manufacturing possano soddisfare alcune esigenze della società, considerando l'evoluzione tecnologica in una prospettiva incentrata sull'uomo. In questo quadro, emerge l'importanza di una revisione sistematica della letteratura, analizzando lo stato dell'arte unito agli aspetti concettuali e intellettuali. Viene proposta una nuova prospettiva teorica, basata sulla tecnologia umana, che considera l'interazione tra tre elementi principali: futuro delle tecnologie, benessere umano e bisogni della società.

Keywords: *human wellbeing; technological trajectories; biomedical implants; societal changes.*

Framing of the research. *La trasformazione digitale e gli sviluppi tecnologici influenzano profondamente ogni aspetto della vita di ogni individuo (Io et al., 2022). Infatti, esse trasformano le attività quotidiane e il funzionamento della società, compresi lo sviluppo economico, i processi lavorativi, i metodi di produzione e i modelli di consumo (Akbari et al., 2020). Secondo (Bernard, 1991), "la tecnologia è il mezzo e il processo attraverso il quale noi, come società, produciamo la sostanza della nostra esistenza". Essa comprende "strumenti, materiali, forme di energia, tecniche e organizzazione del lavoro". Questo approccio, però, non prende in considerazione alcuni aspetti legati al miglioramento della vita delle persone e al soddisfacimento di bisogni individuali e della società (Schivone & MacVaugh, 2009). Tra le diverse tipologie di bisogni (Maslow, 1954), sempre più spesso viene data priorità a quelli psicologici di base e universali, che comprendono la salute, il benessere e la qualità della vita (Deci & Ryan, 2000). Essi non sono cambiati nel corso della storia; ed è proprio lo sviluppo delle nuove tecnologie e la loro applicazione a garantire la creazione di nuovi prodotti e servizi funzionali al soddisfacimento di bisogni universali e non (Park et al., 2012; Bazan, 2019). La tecnologia e la società, infatti, sono due entità correlate, co-dipendenti e si influenzano l'una con l'altra (Appio et al., 2017; Si et al., 2020). Tuttavia, la società sta cambiando e bisogna tenere conto di nuove sfide (Kraus et al., 2021). Si pensi ad esempio al rapido aumento della percentuale di persone di età pari o superiore ai 60 anni, con un conseguente aumento dell'incidenza delle malattie, soprattutto nei Paesi più sviluppati; l'invecchiamento della popolazione genera anche un aumento dell'incidenza delle disabilità sia nei Paesi sviluppati che in quelli in via di sviluppo. Secondo i Centers for Disease Control and Prevention (CDCP), ogni anno negli Stati Uniti circa 54,4 milioni di adulti (circa il 22,7% della popolazione totale) ricevono una diagnosi di artrite, artrite reumatoide, infarti, ictus, lupus o fibromialgia. Quindi, sempre più persone hanno esigenze specifiche che devono essere soddisfatte attraverso dispositivi impiantari come pacemaker, stent o impianti ortopedici per lesioni agli arti, lesioni alla colonna vertebrale, disturbi articolari e difetti craniomaxillofacciali. Gli impianti in ambito medico, infatti, sono in aumento con previsioni che superano il 39% di nuova domanda entro il 2050 (Pabinger et al., 2018). In altre parole, la popolarità dei dispositivi medici impiantati è aumentata vertiginosamente e sono ampiamente accettati come possibile miglioramento della qualità della vita di milioni di persone in tutto il mondo (Global Market Insights, 2023). La maggior parte delle articolazioni artificiali o altri impianti funziona bene e rimane nell'organismo per lungo tempo, facendo emergere la necessità di controlli periodici. Il numero*

sempre più ridotto di chirurghi disponibili per assistere questi volumi crescenti di pazienti rende, però, necessaria la riduzione del numero di procedure di revisione. Inoltre, gli impianti possono creare problemi a causa di infezioni e altre gravi condizioni legate all'ambiente corporeo (Zhai et al., 2023). Tuttavia, l'avvento di nuove tecnologie abilitanti come l'Additive Manufacturing (AM), le frequenti modifiche tecniche e/o produttive e i nuovi design degli impianti sono riusciti a migliorare la funzione e la longevità (Zhang et al., 2023). Infatti, data l'importanza della tecnologia, nell'ultimo decennio sono state condotte numerose ricerche per individuare nuovi metodi e nuove tecnologie avanzate (Qadir et al., 2018). Indubbiamente, negli ultimi anni sono stati compiuti molti progressi e i risultati sono soddisfacenti nel caso degli impianti ortopedici e dentali (Henkel et al., 2013). Dunque, la relazione tra lo sviluppo tecnologico, il benessere umano e la qualità della vita sta diventando un tema rilevante, nel field dell'innovazione e del management dell'innovazione, al fine di comprendere l'impatto della scienza sulla società. Nello specifico, è importante comprendere come l'avanzamento nell'applicazione di nuove tecnologie come l'AM possa seguire traiettorie sostenibili e incentrate sul rispetto dell'"uomo".

Purpose of the paper. Il presente lavoro si propone, dunque, di analizzare l'attuale stato dell'arte attraverso una Systematic-Literature-Review (SLR) che si focalizza sullo sviluppo di tecnologie nell'ambito dei dispositivi biomedici, con il fine di identificare le principali tendenze presenti e future. In questa prospettiva, l'analisi dei trend tecnologici è estremamente utile per arrivare a comprendere lo stato dell'arte e generare informazioni ad alto valore aggiunto sul benessere umano legato alla tecnologia (Canongia et al., 2004; Suh e Sohn, 2015). È proprio analizzando l'evoluzione tecnologica di impianti e protesi mediche che si possono acquisire conoscenze e capire come risolvere i bisogni di una società che cambia, esplorando nuove traiettorie (Dosi, 1982; Ittipanuvat et al., 2014). La qualità della vita è un fattore chiave per gli individui e per la società. Pertanto, lo sviluppo di nuove traiettorie tecnologiche può trasformare la vita di milioni di persone in tutto il mondo e i ricercatori, le aziende e i governi (a diversi livelli) sono chiamati a generare impatti positivi e sostenibili per risolvere i bisogni della società. La valorizzazione della conoscenza deve essere finalizzata alla gestione efficace ed efficiente delle risorse, ma soprattutto a creare un'elevata qualità della vita. Come afferma l'OMS, infatti: "La salute è un investimento, non un costo, la spesa per la salute è un investimento che sostiene la qualità della vita, la felicità e la prosperità"

Methodology. Per questo lavoro è stato scelto un approccio di SLR, rigoroso e pertinente, che produce conoscenza e aiuta a identificare tendenze, percorsi di ricerca e potenziali ricerche future (Kraus et al., 2020, 2022; Lim et al., 2022). Più in dettaglio, secondo Tranfield et al. (2003), la revisione sistematica si basa sui filtri che rendono il processo replicabile, consentendo di ridurre al minimo i "bias" nei risultati. Le principali fasi metodologiche suggerite da studi precedenti per sviluppare una metodologia di SLR, trasparente e replicabile possono essere riassunte nelle "3D" (Dumay, 2010). In particolare, la prima richiede la definizione delle domande di ricerca che rappresentano il passo preliminare nella conduzione di una SLR (Massaro et al., 2016). Il presente lavoro ha l'obiettivo di rispondere alle seguenti domande: quali sono i trend tecnologici nell'ambito della ricerca sui dispositivi implantari? Come le nuove tecnologie possono aiutare il cambiamento umano e sociale? Per rispondere a queste domande di ricerca, è importante progettare un protocollo di revisione, che risponde alla seconda D, per determinare gli articoli da includere per eseguire una ricerca completa del materiale. Seguendo linee guida relative al Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) (Moher et al., 2009; Page et al., 2021) per ridurre al minimo gli errori di interpretazione dei risultati degli studi raccolti, si è passati all'ultima D. Essa prevede lo sviluppo di un quadro di codifica. La metodologia scelta per l'analisi è quella bibliometrica (Kraus et al., 2022), che prevede una mappatura delle parole chiave, dei trend topic, delle co-occorrenze, delle tematiche e della loro evoluzione, delle co-citation e della bibliographic coupling. L'analisi documentale e bibliografica è stata condotta utilizzando la piattaforma Web of Science (Clarivate, 2023) per recuperare tutti i documenti rilevanti sull'argomento. La ricerca parte dal 1985 e arriva fino a fine 2023 per coprire lo sviluppo complessivo dalla pubblicazione del primo articolo sull'argomento. I record inizialmente identificati sono stati 9169 rappresentati esclusivamente da articoli di riviste scientifiche in inglese per identificare i lavori di interesse internazionale. Le categorie WoS non pertinenti riguardanti aree diverse a quelle strettamente legate ai temi in oggetto sono state escluse dalla ricerca, ottenendo un numero finale di 7166 paper. Per l'analisi dei dati sono stati utilizzati strumenti quali il pacchetto Bibliometrix (R-studio) utile per la ricerca quantitativa bibliometrica e di science mapping (Aria e Cuccurullo, 2017).

Results. Questo studio rappresenta uno dei primi tentativi di strutturare un quadro completo che descriva in dettaglio la configurazione delle componenti multidimensionali che dovrebbero essere considerate nello sviluppo di nuove tecnologie. Le revisioni sistematiche della letteratura giocano sempre più un ruolo cruciale nel sintetizzare i risultati delle ricerche passate per utilizzare in modo efficace la base di conoscenza esistente, far progredire le linee di ricerca e fornire spunti basati sull'evidenza nella pratica, oltre ad esercitare e sostenere il giudizio e la competenza professionale (Kraus et al. 2020; Kraus et al. 2022). Il lavoro si propone di capire se e come sia possibile considerare una prospettiva tecnologica basata non semplicemente sul progresso scientifico ma anche umano, orientato ad applicazioni sostenibili ed etiche. I risultati del lavoro dimostrano come lo sviluppo di nuovi dispositivi implantari basati sull'applicazione di tecnologie digitali e innovative può contribuire al cambiamento sociale, migliorando il benessere individuale e collettivo. Si evidenzia, infatti, un cambio di rotta. Si sviluppano sempre più tecnologie mediche che superano gli approcci tradizionali e affrontano un'ampia gamma di problemi di salute e sostenibilità, con un impatto significativo sulla vita degli individui e della società nel suo complesso (Garud & Ahlstrom, 1997; Ittipanuvat et al., 2014). Dal lavoro emerge che i recenti progressi nei biomateriali e le tecniche di produzione stanno rivoluzionando il campo degli impianti medici e anche la vita dei pazienti, offrendo nuove soluzioni promettenti e nuovi vantaggi per la vita umana. I dispositivi medici e le protesi, rappresentano un chiaro esempio di tecnologie applicate alle persone in quanto "esseri umani" (Rose, 1996).

. Si va verso un approccio che può essere definito di “Human Technology”. Infatti, il concetto di Human Technology può essere visto come l'orizzonte che esplora il rapporto tra l'uomo e la tecnologia, sia esistente che emergente e segna un punto di svolta importante, sottolineando il ruolo dell'uomo al centro di ogni applicazione tecnologica innovativa. Questo cambiamento è stato possibile grazie alle tecnologie abilitanti come l'AM che migliorano l'evoluzione aziendale e sociale, permettendo di riconvertire e riutilizzare le vecchie conoscenze all'interno di un nuovo mondo digitale, tecnologico e imprenditoriale.

Questi nuovi impianti e protesi prodotte con tecnologie innovative hanno delle peculiarità che li rendono diversi da quelli convenzionali: rappresentano molto di più di una pura sostituzione. Infatti, la digitalizzazione dei prodotti e dei processi “abilita” la tecnologia ad prospettiva umana favorendo una visione olistica che considera l'uomo nella sua interezza fisica e psicologia, piuttosto che una mera “sostituzione fisica” di un organo (Schiavone & Ferretti, 2021). C'è da sottolineare, infatti la precisione e la possibile personalizzazione dei prodotti finali. A differenza delle tecnologie tradizionali, che spesso impiegano approcci standardizzati, questi dispositivi basati su AM possono essere adattati alle esigenze del singolo paziente, ottimizzando i risultati del trattamento e migliorando l'esperienza dell'utente e la sua condizione psicologica. Quindi, attraverso l'AM è possibile creare impianti su misura che si adattano all'anatomia unica del paziente, migliorandone la funzionalità e riducendo il rischio di complicazioni. Inoltre, impianti su misura più durevoli e biocompatibili riducono la necessità di interventi di sostituzione, riducendo lo stress dei pazienti, ma anche i costi sanitari.

Prendendo in considerazione l'argomento sostenibilità queste soluzioni risultano essere biocompatibili e biomimetiche, imitando il più possibile le funzioni naturali del corpo umano. L'uso di biomateriali (progettati per interagire con i sistemi biologici) e lo sviluppo di nuovi materiali biocompatibili hanno portato a miglioramenti significativi nella durata e nella biocompatibilità degli impianti. Questo approccio riduce il rischio di reazioni avverse e migliora l'integrazione del dispositivo con i sistemi fisiologici del paziente. Le tecnologie tradizionali potrebbero non presentare questo livello di compatibilità, causando potenzialmente maggiori disagi o complicazioni. A differenza delle tecnologie tradizionali, che possono limitarsi a fornire un sollievo sintomatico, alcuni dispositivi medici e protesi moderne mirano a ripristinare o migliorare le funzioni perse. Si tratta di dispositivi che supportano la rigenerazione dei tessuti offrendo mobilità e destrezza, rappresentando una svolta significativa rispetto ai trattamenti convenzionali. Si tratta di applicazioni tecnologiche sostenibili dal punto di vista economico, sociale ed ambientale.

Un altro aspetto da sottolineare, riguarda l'integrazione tra tecnologie IoT (come sensori, analisi dei dati e connettività) e dispositivi medici/protesi basati su AM. Tale caratteristica consente monitoraggi in tempo reale, raccolta dati e gestione a distanza, favorendo un approccio più proattivo e personalizzato all'assistenza sanitaria. Gli impianti “Smart” sono progettati per monitorare e rispondere ai cambiamenti del corpo del paziente, rendendoli ideali per condizioni come il diabete o le malattie cardiache. Le tecnologie tradizionali sono in genere prive di tali funzioni limitando la loro capacità di adattamento dinamico alle esigenze del paziente. Anche l'ottimizzazione delle prestazioni nel tempo è possibile grazie a sistemi adattivi e di apprendimento, che consentono ai dispositivi di evolvere nel tempo. Con l'aiuto di algoritmi di apprendimento automatico è possibile analizzare i dati del paziente in modo da regolare le impostazioni del dispositivo per adattarlo meglio alle esigenze individuali e della società. Anche in questo caso, queste peculiarità non sono presenti nelle soluzioni tradizionali.

I dispositivi medici e le protesi stanno rivoluzionando l'assistenza sanitaria fornendo soluzioni più accurate, intelligenti e incentrate sul paziente rispetto alle alternative tradizionali. Con il rapido progresso della tecnologia, le possibilità di diagnosi, trattamento e riabilitazione sono in continua espansione (Gastaldi et al., 2018). Questo promette un futuro in cui l'assistenza sanitaria non solo sarà più efficace, ma anche adattata alle esigenze specifiche di ciascun paziente. Le tecnologie umane rendono la nostra vita facile, comoda, sana e piacevole e possono supportare gli esseri umani, ridisegnando processi e prodotti. In questo modo, la tecnologia migliora la nostra vita attraverso la sua continua evoluzione che si traduce in funzionalità sempre più avanzate (Cho et al., 2009).

La recente pandemia ha messo in luce la nostra dipendenza dalla tecnologia. Tuttavia, è emersa la necessità di creare tecnologie che abbiano una resa per l'essere umano più riconoscibile ispirando fiducia. Di giorno in giorno, l'esigenza di creare “tecnologie umane” diventa più forte e richiede una forte integrazione con l'etica. È innegabile che il rapporto tra uomo e tecnologia è caratterizzato da grandi opportunità che hanno posto le basi per il progresso tecnologico dell'umanità. Tuttavia, a differenza del passato, stiamo assistendo a un nuovo fenomeno che vede la tecnologia stessa adattarsi alle esigenze di chi la utilizza, umanizzandosi (Galimberti, 2009). Probabilmente, nel prossimo futuro, assisteremo a una rapida fusione tra uomo e macchina in cui la nostra umanità sarà “incorporata” nella tecnologia. Quello che stiamo vivendo è uno dei momenti più rivoluzionari della storia dell'umanità che pone la tecnologia al centro di un cambiamento epocale come strumento per migliorare le nostre capacità umane (Marchiori et al., 2022). Oltre ai cambiamenti funzionali nella vita quotidiana, le tecnologie umane hanno effetti sul benessere sociale ed emotivo. Migliorano le capacità fisiche, ma il loro impatto si estende alla sfera della salute mentale. Infatti, ripristinando la fiducia in sé stessi, promuovendo l'indipendenza, facilitando l'integrazione sociale, favorendo l'adattamento psicologico e ispirando un senso di possibilità, le protesi potenziano gli individui e contribuiscono al loro benessere mentale complessivo. È fondamentale riconoscere e dare priorità al profondo impatto che questi dispositivi hanno sulla salute mentale, consentendo alle persone di affrontare la vita al meglio.

Infine, i responsabili delle politiche sanitarie la prevenzione, l'autogestione e il trattamento delle malattie croniche come una sfida importante (Nolte & McKee, 2008). Di conseguenza, gli sviluppi tecnologici a favore della salute sono

sempre più posizionati nel contesto più ampio del sostegno a un invecchiamento attivo e sano e a una vita indipendente (Cabrera & Malanowski, 2009; Peine & Moors, 2015). Le nuove tecnologie consentono alle persone di evitare la stigmatizzazione sociale che, a sua volta, permette la loro integrazione sociale e la riduzione dei problemi emotivi legati a disabilità e carenze fisiche e psicologiche. Pertanto, la sfida dell'innovazione non risiede più solo nel potenziale economico, ma anche nei cambiamenti sociali; il processo innovativo sta evolvendo verso forme di co-sviluppo sempre più marcate. Il sapere scientifico e l'applicazione tecnologica devono essere sviluppati portando sempre il paziente “al centro”; questa rappresenta una traiettoria tecnologica con un forte impatto sociale e non solo economico (Ittipanuvat et al., 2014; Kwon & Park, 2018).

Research limitations. Questo lavoro non è esente da limitazioni. Infatti, si tratta di una prima analisi sistematica della letteratura che abbraccia più discipline, finalizzata a spiegare fenomeni altamente mutevoli. Future ricerche si stanno focalizzando sull'analisi brevettuale e sulle dinamiche competitive.

Managerial implications. I cambiamenti sociali richiedono agli individui e soprattutto agli attori aziendali di comprendere sia le esigenze tecnologiche che quelle sociali per generare l'innovazione. Le tecnologie richiedono una prospettiva umana nello sviluppo tecnologico; c'è bisogno quindi, di modelli di “co-sviluppo” che concilino il progresso tecnologico, quello umano e i bisogni della società (Schiavone & Ferretti, 2021). Ciò implica una transizione che cambia radicalmente lo scenario dell'innovazione, determinando l'erosione dei classici principi guida del business basati sull'orientamento a breve termine con obiettivi di mero profitto. Questo richiede lo sviluppo di un nuovo approccio al business, dettato da un cambiamento globale verso una tecnologia umana che supporta il benessere collettivo. Di conseguenza, le imprese che applicano le nuove tecnologie proponendo nuovi prodotti/servizi/processi devono riconfigurare la loro value proposition (cosa viene offerto) e rimodellare il business model (Berman, 2012; Weill & Woerner, 2013; Metallo et al., 2018), proponendo nuove dimensioni del “valore”. Quindi, accanto al valore economico e contabile, si devono promuovere nuove dimensioni che includono l'etica e la sostenibilità (Fasbinder, 2010; van Noort, 2012). Lo studio, dunque, propone una visione sia tecnica che manageriale, fornisce una SLR multidisciplinare e offre anche una discussione approfondita sulle questioni manageriali che le aziende dovrebbero affrontare nel prossimo futuro.

Originality of the paper. Sebbene la letteratura sull'argomento sia in espansione, soprattutto in termini di prospettiva tecnologica, nessuno studio ha offerto una prospettiva multidisciplinare incrociando la letteratura tecnico/ingegneristica con quella di management (Shichman et al., 2022; Subbiah Ponniah et al., 2023). Il nostro studio propone un esame delle traiettorie tecnologiche nel campo degli impianti e delle protesi biomediche per capire se e come l'evoluzione tecnologica si muove verso una prospettiva incentrata sulla creazione di valore e non di profitto (Kwon & Park, 2018). La comprensione del topic dal punto di vista tecnologico e di business è fondamentale poiché offre spunti di ricerca futuri finalizzati ad analizzare la struttura dell'industria e del settore, anche attraverso lo studio della letteratura brevettuale (Bhat, 2005).

Well-being in the transition from Industry 4.0 to Industry 5.0

MICHELA PICCAROZZI¹ FEDERICA CABONI² ROBERTO BRUNI³

Abstract

The Industrial Revolution marked the evolution of society through technological development and the introduction of innovations. In the current scenario, we are experiencing a coexistence of two revolutions. The first, Industry 4.0 focused on the automation and digitization of production. The more recent, Industry 5.0 is oriented towards the centrality of human beings' production processes and in general in the development of a sustainable society. Both revolutions have brought value growth, primarily to companies, to the global economic system and society at large by improving work, employment and general creating well-being. The purpose of this research work is to analyse how Industry 4.0 and Industry 5.0 contributed and continue to contribute to well-being creation. Field, output and technologies involved in well-being creation will be investigated with a systematic literature review and a content analysis highlighting contact points and differences between the two revolutions and the evolution of the scenario at this time of transition. Managerial implications and limitations are included in the analysis.

Key words: Industry 4.0; Industry 5.0; well-being; transition; systematic literature review; content analysis.

Framing of the research. Industrial revolutions have historically initiated radical processes of change and development in production systems, labour dynamics and society as a whole (Xu et al., 2018; Sharma and Sing, 2020). Each revolution has brought new opportunities, introduced new technologies and placed new challenges and demands on society (Boninsegni et al., 2022). This has all contributed to the creation of new levels of prosperity but has also revealed weaknesses and difficulties in applying and integrating human beings and technological innovations above all (Koc and Teker, 2019). In the current economic and social context, we are witnessing the coexistence of two industrial revolutions (Leng et al., 2022). The first one, Industry 4.0, which has been underway since around 2010, has now reached a wide application and internalisation from the business to the social context. The second, Industry 5.0, has recently started a process of revision of the previous paradigm aimed at affirming the centrality of human beings and social sustainability at the core of technological development (Nahavandi, 2019; Breque et al., 2021).

The impacts of the two revolutions have been at the centre of scientific debate, for years with the topic of Industry 4.0 and more recently in Industry 5.0 perspective (Xu et al., 2021). Numerous aspects and areas were analysed and the contributions of the two revolutions were assessed (i.e. production efficiency, sustainability, performance, etc.), including the study of the possible impact in terms of well-being creation (Hanefah, 2018; Kadir and Broberg, 2020).

Well-being can be considered a multifaceted and complex concept (Halbreich, 2022) often associated with innovation and technological development, even in a controversial way (Orben and Przybylski, 2019). The concept of well-being is derived from the combination of a set of factors such as prosperity or quality of life, and quality of social relations, referring to the mental, physical, economic or emotional sphere of the person (Fletcher, 2016). Well-being can thus be considered in the sphere of the worker, in that of the consumer and/or citizen, and in that of the natural environment, opening up different scenarios that from the individual allow one to consider the perspective of society as a whole and thus of general well-being (Kadir and Broberg, 2020).

In this context, the two revolutions have and are currently making their contribution to creating favourable conditions for the implementation of well-being dynamics (Xu et al., 2021). Often, the focus of studies in this lens is based on the enabling technologies of the two revolutions, which are considered the operational tools driving the evolution and changes taking place, including those concerning well-being (Zizic et al., 2022).

In this context, the literature is beginning a debate comparing the two revolutions, starting to investigate the foundations of well-being and the dynamics of creation (Xu et al., 2021). This extended abstract aims to fit into the current scientific debate by attempting to focus on the characteristics of well-being between the two industrial revolutions and in a transitional perspective.

Purpose of the paper. Starting from the literature analysis, the extended abstract aims to analyse how Industry 4.0 and Industry 5.0 have contributed and continue to contribute to well-being creation. Field, output and technologies involved in achieving well-being will be investigated to analyse points of contact and differences between the two revolutions and to understand the evolution of the scenario in this time of transition.

Methodology. The analysis was conducted through a systematic literature review and a subsequent content analysis of the selected papers (Abatecola et al., 2013). The systematic literature review was implemented following the methodological scheme proposed by Mayring (2004) and Denyer and Tranfield (2009). Four analysis steps enabled the selection of the sample of papers to be investigated using content analysis: materials collection, descriptive analysis, categories selection and analysis of sample materials. The papers were extracted from the Scopus database, considered one of the most relevant and comprehensive databases internationally in management studies (Newbert, 2007; Merli et al., 2018; Sassanelli et al., 2019). Two different searches were implemented: the first using the keywords “Industry 4.0” and “well-being” (266 papers have resulted from the research), the second “Industry 5.0” and “well-being” (109 papers). The results were filtered by considering papers in the areas of “business, management, accounting”, “social science” and “decision science” (91 papers in the field of Industry 4.0 and 42 papers in Industry 5.0). Subsequently, only papers in English published in Journals with peer review were selected to increase the reliability of the information (39 papers and 20 papers). Finally, the abstract reading with an inclusion/exclusion approach, made it possible to exclude papers that were not significant about the research objective (29 papers and 18 papers). The final papers (47 papers) were downloaded and analysed in an organised Excel database to extract general information (i.e. year, journal, methodology) and to start the content analysis (Mayring, 2004). Table 1 summarises the outline of the methodology.

Table 1 - Methodology outline

Sistematic review step	“Industry 4.0” + “well-being” n. papers	“Industry 5.0” + “well-being” n. papers
Keyword search	266	109
Subject area selection	91	42
Paper characteristics selection	39	20
Abstract reading	29	18
Total	47	

Source: Author elaboration

Results. The analysis of the results was divided into two sections. In the first one, the general aspects of the papers were analysed to understand their characteristics and evolution over time (year of publication, journal and methodology). In the second section (by the application of content analysis), the specific research aspects of the individual papers were investigated about: field, output and technologies involved in achieving well-being.

The analysis of the publication time frame shows a concentration of articles in the years 2021-23 (Figure 1).

Figure 1 - Publication trends

Source: Author elaboration

From the point of view of the methodology used, we can say that 70% of the papers are empirical and thus bring concrete validation of the considerations regarding the two revolutions and the well-being created. Regarding the editorial placement of the papers, for Industry 4.0 we find among the journals with the most recurrences: Sustainability (4 papers, 14% of the sample), International Journal of Production Research (3 papers, 10%), International Journal of Industrial Ergonomics (2 papers, 7%) and Technology in Society (2 papers, 7%). The remaining papers (18 papers) are placed in journals dealing with production, environment, and quality. However, regarding papers on Industry 5.0, a prevalence of recurrences emerges in the journals: International Journal of Production Research (3 papers, 17% of the sample), Systems (3 papers, 17%) and Sustainability (2 papers, 11%).

The second section of results, which emerged from the content analysis of the selected papers, provides information on the field, output and technologies involved in achieving well-being.

Table 2 shows where, according to the literature, the two industrial revolutions are read in terms of well-being creation.

Table 2 - Industry 4.0 and 5.0 well-being field results

Industry 4.0	n.	%	Industry 5.0	n.	%
Industry in general	5	17%	Production	7	39%
Production	5	17%	Firms organisation	4	22%
Society in general	5	17%	Society in general	3	17%

Education	3	10%	Maritime Industry	1	6%
City	2	7%	Agriculture Industry	1	6%
Supply Chain	2	7%	Supply Chain	1	6%
Aviation Industry	1	3%	Total	18	100%
Ittic Industry	1	3%			
Tourism Industry	1	3%			
Total	29	100%			

Source: Author elaboration

Industry 4.0 seems to lead to well-being both in the industrial sector in general (i.e. Reiman et al., 2021; Cierniak-Emerych and Golej, 2020) and in companies about production (i.e. Alves et al., 2024; Lind et al., 2023) and related processes (Blandino et al., 2023), even in specific areas e.g. tourism (Gani et al., 2023). It also supports well-being in society in general as well as in specific areas (e.g. cities and education) (Abulibdeh et al., 2024).

Industry 5.0 on the other hand seems to give a boost to well-being starting from the enterprise, not only in production (i.e. Narkhede et al., 2024) but in the redefinition of business organisation (Galvan-Vela et al., 2021; Vijayakumar and Sobhani, 2023), especially as a result of the new technologies introduced (see Table 4 and related commentary). Here too, specific sectors emerge where the authors highlight the contribution to well-being (i.e. agriculture) and a general impact on society (Ferreira et al., 2022; Žižek et al., 2021). This initial analysis shows how welfare creation is associated with the two revolutions in both general and specific areas, suggesting different beneficiaries and different meanings of this.

The second level of analysis allows a detailed approach to well-being by trying to investigate its characteristics, i.e. how it is concretely expressed and what output it yields in the areas that emerged previously.

Table 3 shows how the prosperity created by the Industrial Revolution is interpreted and where it resides.

Table 3 - Industry 4.0 and 5.0 well-being output results

Output - Industry 4.0 and well-being	n.	%	Output - industry 5.0 and well-being	n.	%
Working conditions	19	65%	Working conditions	10	56%
Living conditions	4	14%	Environmental and social issues	4	22%
Environmental and social issues	6	21%	Living conditions	4	22%
Total	29	100%	Total	18	100%

Source: Author elaboration

In the case of Industry 4.0, its application has led to well-being which can be interpreted as a substantial improvement in working conditions. In this case, the considerations emerge from the companies and the advantages of the innovations of the fourth revolution brought to workers. The first aspect that emerges is the consideration of well-being as a reduction of work stress (Apraiz et al., 2023; Blandino, 2023; Dobrowolska et al., 2022). Industry 4.0 seems to have created the conditions for an effective improvement of the working environment, entrusting repetitive and thoughtful tasks to machines, contributing to enhancing system efficiency while at the same time implementing worker well-being (Slama et al., 2023). Koropets and Tukhtarova (2021) state how this improvement is also strengthened by an increase in jobs linked to innovation. This well-being is also qualified as mental (Cierniak-Emerych and Golej, 2020) and psychological (Alessio et al., 2019) and is generally linked to the sphere of the worker's health in particular of the ageing workforce (Alves et al., 2024). Kolot et al. (2020) talk about the social quality conveyed by Industry 4.0 as the ability to increase well-being and clarify one's potential, therefore also contributing to the growth of workers' awareness of their abilities and skills (Reiman et al., 2021). From an organizational point of view, Industry 4.0, together for example with Lean Manufacturing, jointly influences the concepts of Job Enlargement and Job Enrichment, creating the basis for greater efficiency and worker satisfaction (Cimini et al., 2023).

As regards Industry 5.0, also in this case the well-being created primarily reaches workers and the working environment. This aspect is certainly strengthened by the underlying logic of Industry 5.0, the centrality of man, from which a true human-centred workplace design philosophy derives (Ashta et al., 2023). Attention is focused not only on practical working conditions but emotional aspects also come into play, "emotional intelligence" for example, which is

considered a true soft skill (Chin et al., 2021). The well-being of the worker is certainly driven by the numerous and interactive new technologies (i.e. Cobots) that allow us to work alongside humans, support them but not replace or demote them (Nourmohammadi et al., 2022).

In equal measure, between the two revolutions, well-being emerges as an improvement in living conditions. This is often associated with the strong interactivity and involvement of the innovations introduced, capable of improving the Indoor environment (Broday et al., 2023) of the daily life of each individual, even going into detail about certain categories such as students (Rochin Demong et al., 2023).

Finally, environmental and social issues are the other results in which the well-being created by the two revolutions is expressed to an almost comparable extent. For instance, well-being is understood as strengthening food security, improving the performance of electricity infrastructure, enabling citizen involvement and participatory adaptation as well as reducing the impact of climate risks (Balogun et al., 2020).

The last level of analysis allowed us to focus attention on the specific enabling technologies of Industry 4.0 and the emerging ones of Industry 5.0 which are considered by the authors as supporters of the creation of well-being.

Table 4 shows the technologies that emerged from the analysis of the two revolutions. Not in all papers is there a specific technology to which the creation of prosperity can be linked, in some cases the reference is only general to the industrial revolution examined.

Table 4 - Industry 4.0 and 5.0 technologies involved in well-being

Technologies I4.0 involved in well-being	n.	%	Technologies I5.0	n.	%
Artificial Intelligence (AI)	3	20%	Automated Guided Vehicles (Agvs)	1	13%
Cyber-physical systems (CPS)	2	13%	Cobots	1	13%
Internet of Things (IoT)	2	13%	Exoskeletons	1	13%
Smart manufacturing	2	13%	Pick and Transport Robot (PTR)	1	13%
Blockchain	1	7%	Big Data	1	13%
Lean manufacturing	1	7%	Augmented Reality (AR)	1	13%
Machine Learning (ML)	1	7%	Internet of Things (IoT)	1	13%
Motion capture (MOCAP)	1	7%	Others	1	13%
Virtual Reality (VR)	1	7%	Total	8	100%
Smart Tourism Technologies (Stts)	1	7%			
Total	15	100%			

Source: Author elaboration

In the case of Industry 4.0, a technology that is in some cases associated with well-being is AI. AI is associated both with worker well-being and as a support for environmental and social issues (Murugesan et al., 2023; Abulibdeh et al., 2024). IoT as well as CPS, thanks to their sharing and interoperability capabilities, also allow substantial improvements in terms of safety, risk prevention and ergonomics (Velasco et al., 2022).

In the case of Industry 5.0, although we are still in the initial phase of studying this revolution, technologies oriented towards collaboration between man and machine are already emerging. For example, Cobots, are collaborative robots, which can improve the productivity and well-being of workers by determining the optimal allocation of tasks and available resources (Nourmohammadi et al., 2022) and at the same time monitor the working conditions and the state of mind of the worker to issue alerts and prevent problems (Storm et al., 2022). Automated guided vehicles (AGVs) can also facilitate collaboration between man and machine, bringing man to the centre of the system and improving performance and employee well-being (Thylén et al., 2023). Thanks to these tools and others (i.e. exoskeletons) it is possible to create a personalization of the working environment, improving workforce well-being and capabilities (Ashta et al., 2023).

It is clear from the analysis of the results that both Industry 4.0 and Industry 5.0 have contributed and are continuing to fuel the well-being creation process at various levels, both for companies and for society at large. The well-being highlighted by the authors is concretely linked to the sphere of the worker, but not only. Indeed, we have a propagation of the effects of the Industrial Revolution under consideration to citizens, students and cities as a whole. The scope of innovations and their beneficial impact is strongly linked to companies and their production processes in the Industry 4.0 paradigm, and, starting from the workers it spreads to the society at large with the Industry 5.0 model. Although the latter revolution is just getting underway and being studied, the contributions of some new enabling technologies to the overall well-being of business, workers and society are already clear. The transition from Industry 4.0 to Industry 5.0 seems to have this focus on human beings as a guiding thread, which is much more pronounced in the new 5.0 scenario and reinforced by the clear statement of sustainability as the cornerstone. Therefore, well-being is confirmed as an aspect linked to the two revolutions and driving the transition to Industry 5.0. Well-being is not always stated but implied and strongly connected with innovation and technology. Statically analysing the results that have emerged from the two revolutions, both seem to have as a more or less explicit objective the creation of wealth. In a dynamic vision, however, Industry 5.0 will, in our opinion, have to go more and more into the details of the components and determinants of well-being with a view from the particular to the specific and vice versa, trying to monitor needs and prevent needs. The switch of the logic is determined; society passes from the adoption of technology to improve production efficiency to the adoption of technology to multiply the perceived well-being inside and outside the companies.

With these transitional dynamics, the new Industry 5.0 scenario can aspire to be seen as an evolutionary step towards the '6.0 Wellbeing Society' (Žižek et al., 2021), where people will be able to define the parameters of their quality of life and achieve them thanks to innovation and increasingly widespread enabling technologies.

Research limitations. The limitations of this extended abstract should be considered and evaluated. From the point of view of methodology, the choice of keywords can be considered a limit. Indeed, the selection of words, while limiting the analysis to the specific issue, may not take into account the synonyms used by some authors (e.g. Fourth Industrial Revolution) and thus limit the analysis. In addition, findings emerge in this research that link Industrial Revolutions to well-being always in a positive sense. An extension of the research could consider the negative and/or controversial aspects of innovations to create a comprehensive view of the phenomenon. Moreover, the research work is, at this stage, merely conceptual and therefore lacks empirical validation of some of the considerations that emerged.

Managerial implications. This study endeavours to offer a theoretical contribution by methodically reviewing and critiquing the literature on well-being throughout the First and Second Industrial Revolutions, scrutinizing its distinctive features and exploring the influence of technological advancements on fostering well-being. From a management perspective, the analysis seeks to stimulate contemplation among corporations, institutions, and, on a broader scale, policymakers, regarding how these industrial transformations and the ongoing shift are contributing to well-being enhancement. A detailed examination of the intersections between Industry 4.0 and 5.0 with well-being reveals the innovation potential and its capacity to augment the systems' effectiveness and efficiency.

More explicit knowledge of the expected output of innovation can drive investment choices in equipment, company reorganisation or human resources and skills. Moreover, although what emerges from the literature is not very detailed, knowing the role of individual enabling technologies in supporting well-being and understanding their transition between the two revolutions could address managerial choices as well as institutions in creating supports and incentives for the adoption of such tools to achieve widespread well-being, from the workplace to society as a whole. I5.0 could lead to new managerial practices that should consider technology as a useful tool for freeing up workers' time and transforming work activity into an additional opportunity for building the social life of individuals. At the same time, new business strategies and market relations could arise where competition should be generated on the ability to create well-being in companies and society.

Like every innovation, I5.0 and further evolutions present some emerging limitations. First people involved directly or indirectly are continuously producing data useful for main internet and high-tech companies and, consequently, they can concentrate their power on markets and societies. Secondly, people may be increasingly connected to technologies and may increase their dependence on the internet and machines, further limiting their ability to appreciate well-being outside of these contexts.

Originality of the paper. The extended abstract deals separately and comparatively with the issue of well-being in the two Industrial Revolutions. The originality lies in the attempt to provide a holistic and evolutionary view of the concept of well-being creation in the two moments and frameworks that coexist today, Industry 4.0 and Industry 5.0. At the same time hypothesizing development trends in this transition phase.

Employee well-being in the era of hybrid work: In search of sustainability for organizational members

ALFONSA BUTERA¹ ALESSANDRA MAZZEI² SILVIA RAVAZZANI³

Abstract

Employee well-being is a multidimensional concept that companies globally are increasingly taking into consideration in their search for a sustainable business. Addressing the issues related to employee well-being has become more complex because of the rise of remote working, which today is permanently adopted by a large number of companies through hybrid work models.

The purpose of this study is to explore how Italian companies address the issues related to employee well-being, which practices they implement to sustain it, and if and how they perceive and face the challenges that remote working creates for employee well-being through specific interventions.

The empirical study is based on the accounts of managers from 10 Italian companies. Qualitative data were collected from 10 interviews carried out between July and October 2023.

Findings show that Italian managers have a multifaceted understanding of employee well-being, with a focus on physical and psychological well-being, and are aware of the influence of management style, which is linked to a workplace dimension of well-being, on the overall level of well-being. Companies in the sample implement a broad spectrum of initiatives and practices, mainly devoted at addressing physical, psychological, and life well-being, where the latter relates to work-life balance and family happiness. Regarding the challenges that remote working creates for employee well-being, companies appear to be only partially active in addressing them.

While the study is at its preliminary stage and the number of companies involved does not allow to make any generalizations, these evidence-based insights can be a solid base for designing a more comprehensive study.

The findings of this study suggest managers to look at employee well-being in a multifaceted way: they should take care of the workplace, physical, psychological, life, and social components of employee well-being by implementing specific practices devoted to sustaining each of them. Moreover, managers should pay specific attention to addressing the risks for employee well-being introduced by remote working: professional and social isolation, as well as blurring boundaries between work-life and private life when working from home.

While it explores Italian companies' approach to employee well-being, this study offers insights regarding the initiatives and practices that organizations are implementing to mitigate the negative effects of remote working on employee well-being in the post-pandemic era, when hybrid work models are becoming permanently adopted.

Key words: *employee well-being; employee health; remote working; hybrid work models; well-being practices; sustainable workplaces.*

Framing of the research. *Employee well-being is a multifaceted concept that has been studied from several perspectives. From an organizational perspective, Zheng et al. (2015) distinguished three dimensions of employee well-being: workplace well-being, life well-being, and psychological well-being. Workplace well-being includes work-related elements, such as compensation and benefits, labor protection, logistics service, management style, and work arrangements. Life well-being and psychological well-being refer to dimensions related to work-life balance, family happiness, emotional health, personal growth, and environment mastery. This means that managers should not only focus on employees' job satisfaction but also show genuine concern for employees' life well-being and psychological well-being when addressing this topic overall.*

Similarly, from a management perspective, Grant et al. (2007) notice that employee well-being cannot simply be viewed as job satisfaction or the overall quality of an employee's experience and functioning in the workplace. In their

e-mail: alessandra.mazzei@iulm.it

³ IULM University
e-mail: silvia.ravazzani@iulm.it

vision, it encompasses three components: psychological, referring to subjective experience and functioning; physical, referring to bodily health and functioning; social, referring to relational experience and functioning.

In the management stream of studies, differently Danna and Griffin (1999) distinguish well-being and health. Well-being comprises life and non-work satisfaction enjoyed by individuals (i.e. satisfaction with social life, family life, recreation, spirituality) together with work and job-related satisfaction (i.e. satisfaction with pay, promotion opportunities, the job itself, co-workers), while general health refers both to mental or psychological health and physical health within a more medical context (e.g. reported symptomology or diagnosis of illness or disease). Therefore they suggest that the term health should be applied to organizational contexts when specific physiological or psychological indicators are of interest, while well-being should be used as appropriate to include context-free measures of life experience (e.g. life satisfaction) and generalized job-related experiences, such as job satisfaction or job attachment, as well as more facet-specific dimensions, such as satisfaction with pay or co-workers.

In sum, literature proposes different models and constructs of well-being: while the psychological and physical components are typically included, other dimensions vary. Some authors put the accent on elements more related to the organizational context and to life well-being, others underline the role of social well-being experienced in the relational realm of the organization. Finally, some authors propose to differentiate employee well-being from employee health when mental or psychological health and physical health are concerned within a more medical context.

In recent years, the Covid-19 pandemic made organizations and society at large re-discover the importance of well-being and underlined the relevance of mental health and the social component of employee well-being, in a moment when the recourse to remote working suddenly increased in numerous organizations.

With reference to Italy, several studies were conducted to investigate the effects of remote working on employee well-being and productivity during the pandemic (e.g., Biasi et al., 2022; Molino et al., 2020; Spagnoli et al., 2020; Toscano et al., 2020). Biasi et al. (2022) showed that in the first phase of Covid-19 pandemic employees involved in the study reported perceptions of higher productivity while remotely working, even if results show that, for the period under investigation, remote working did not affect productivity. Their study also showed that remote working had consequences on personal well-being that differed among genders, with especially women struggling to reconcile between professional and personal needs. Spagnoli et al. (2020) focused on two counter-effects of remote working experienced by employees during the pandemic, namely: workaholism, the tendency to work excessively hard and to be obsessed with work; and technostress, the stress experienced by end users in organizations as a result of their intensive use of ICTs. Their study underlined the moderating role of leadership on such risks for remote employees. Similarly, Molino et al. (2020) confirmed the negative effects of technostress on employee well-being during the pandemic, and alerted about the “always on” working practice encouraged by remote working, which challenges employees in terms of mental and physical fatigue. Toscano et al. (2020) showed instead the deleterious role of social isolation for employee stress.

Regarding the consolidation of hybrid work contexts after the pandemic, Mazzei et al. (2023a) underlined the risk of a deterioration in the relational realm of the workplace. In a second study specifically focused on newcomers, Mazzei et al. (2023b) alerted that workplace social isolation due to remote working can reduce the efficacy of the onboarding process for new employees.

In other national contexts, with reference to Australian employees, Franken et al. (2021) explored the challenges associated with working remotely and resources for well-being and productivity. Most employees involved in the study expressed their feelings of happiness and satisfaction while working flexibly from home, but a number of them reported feeling overwhelmed and stressed about the heightened and competing demands, as well as isolated, both personally and professionally. Professional isolation caused a diminished sense of trust in co-workers and managers to accomplish their job responsibilities. Other stressors emerged concerning childcare responsibilities and managing the distraction of partners.

Ambivalent results regarding the effects of remote working on employee well-being and productivity emerged also from the meta-analyses conducted by Charalampous et al. (2019) and Ferrara et al. (2022). On the one hand, the study conducted by Charalampous et al. (2019) highlights that, while there is a general positive effect of remote working on employees' emotions, job satisfaction, organizational commitment levels, and autonomy, there is also a risk of social and professional isolation and perceived threats to professional advancement. On the other hand, the study conducted by Ferrara et al. (2022) reported that remote workers show higher positive affective well-being and higher happiness especially when they are highly resilient, but mixed results emerge on the role of teleworking on work-life balance. These results show that the perceived well-being levels when working remotely are influenced by the ability to manage the boundaries between work-life and private life. The authors of both these studies suggest that this heterogeneity can be influenced by the employees' characteristics as well as the organizational context and culture's characteristics.

Considering the increasing diffusion of hybrid work models, Hopkins and Bardoel (2023) proposed five pillars for successful hybrid work following a qualitative study on HR managers in Australia. These five pillars refer to operations, culture, communication, well-being, future skills, and technology. With specific reference to well-being, Hopkins and Bardoel recalled the relevance of dealing with mental health and well-being when remote workers are concerned. First of all, this implies an effort by managers to regularly check the well-being of their team members. Organizations can also implement specific initiatives to sustain psychological, physical, and social well-being: for instance, mental health aid specifically focused on dealing with remote working issues, initiatives to ensure remote employees have ergonomically compliant home office setups, training virtual exercise classes or challenges (e.g., daily step count), virtual team lunches and coffee breaks, online quizzes, book clubs, and movie nights.

Purpose of the paper. *Well-being is becoming an increasingly important topic on the agenda of companies worldwide due to the greater sensitivity that people pay to this aspect in relation to their job after the pandemic, when employees especially experienced new or exacerbated mental health issues. Moreover, the hybrid working models that companies today are largely adopting generate new challenges for employee well-being due to remote working. Therefore, the purpose of this study is to explore how Italian companies address the issues related to employee well-being today. First, it investigates what Italian companies mean for employee well-being. Second, it explores the practices they implement to sustain the well-being of their employees. Third, with reference to the spread of hybrid work models, this study also examines if and how Italian companies perceive the challenges that remote working creates for employee well-being and how they possibly face these challenges through specific interventions.*

Methodology. *This exploratory study (Yin, 1994) was guided by three research questions: 1) How do Italian companies address the issues related to employee well-being? 2) What practices do they implement to sustain it? 3) Do they recognize the challenges that remote working poses to employee well-being and tackle them through specific interventions?*

Considering its exploratory nature, researchers opted to conduct the empirical study leveraging the accounts of managers from 10 Italian companies. Qualitative data were collected from 10 interviews carried out between July and October 2023, either face-to-face or online, through a semi-structured interview guide with open-ended questions. Interviews lasted about 2 hours each. The convenience sample of the 10 interviewees, one for each company in the sample, was built leveraging the relationship networks of researchers and included board members and managers responsible for employee well-being, sustainability, HR management, and internal communication. Companies were selected to build a diversified sample in terms of company size and sector. Special attention was given to the fact that companies had adopted a hybrid way of working, with employees working both remotely and at the company's sites.

Within the company sample, 8 companies out of 10 are multinational organizations, and 6 out of 10 have Italian origins. They operate in multiple industries, with 4 manufacturing companies and 6 service companies. Regarding company size, 6 are large organizations with more than 5,000 employees, 3 are medium-sized organizations with up to 3,000 employees, and 1 is a small organization with about 200 employees. To answer the research questions, researchers conducted a thematic analysis of the data without the support of any software: emergent data were parsed to find recurrent themes, concepts, and dimensions.

Results. *Considering the first research question, which is the meaning that Italian companies attribute to employee well-being, most interviewees include two dimensions in their definition of employee well-being. The first dimension is related to nutrition, physical movement, and sport: this recalls the physical dimension of well-being (Grant et al., 2007) and health (Danna & Griffin, 1999). The second dimension recalled is the psychological one (Grant et al., 2007; Zheng et al., 2015). Moreover, all companies involved in the study recognize the role of management style, which can be intended as part of workplace well-being (Zheng et al., 2015) and as the most impacting factor on the overall level of employee well-being. According to all interviewees, management style comes before any specific initiative or practice implemented to improve employee well-being: in the words of one interviewee, "We must be aware that people's well-being is not just the prerogative of those who have the organizational label for this topic. Company leaders must first and foremost transmit this culture".*

One interviewee broadens the definition of employee well-being also to other components that are related to the workplace context, specifically linking the state of well-being to the simplification of work processes, methodologies, and tools. The question of well-being then becomes related to the facilitation of work within the organization and to what produces value in everyday life for people: "If I have a salesman who spends 70% of his time on administrative activities that are not his responsibility, I can also give him a meal voucher a day, but he is at risk of leaving the company because he will look for his professional life elsewhere, where he can express himself best".

With specific reference to the psychological dimension of well-being (Grant et al., 2007; Zheng et al., 2015), some interviewees emphasize the relevance of self-expression: well-being is generated by a set of material (e.g., a process) and immaterial (e.g., organizational culture) elements that allow people to flourish in a eudemonic way. In this sense, employees cannot experience a state of authentic well-being if they do not live in an environment that allows them to express their potential: as one interviewee states, organizations should foster "everything that allows people to flourish, the possibility for people to find in their work a means to express the best of themselves".

Some interviewees understand the provision of employee well-being in general terms as the result of the relationship between people and the organization. For instance, an interviewee recalls: "It's the way our people experience their relationship with the company, this is our common thread. We are committed to promoting and maintaining the physical, mental, professional, and socioeconomic well-being of our people. We do it through the correct circulation of information, trust, flexibility, collaboration, and motivation, which for us are fundamental elements so that people feel part of the company and share its values".

Lastly, some interviewees underline the flexibility of the concept: no one well-being model fits all employees. People's needs are very different, so well-being management implies actively listening to needs and having a portfolio of options to meet people's diverse needs, while respecting the company's objectives.

Considering the second research question of this study, that is what practices Italian companies implement to sustain the well-being of their employees, the data collected allows to depict a composite and heterogeneous framework of initiatives.

With reference to the workplace dimension of employee well-being, some companies recall the transparent communication of organizational decisions and processes such as evaluation and career development, as well as profit sharing with employees. In one case, a dimension of justice in terms of compensation is also highlighted as an example of organizational intervention with a strong impact on commitment and well-being.

In many cases, companies implement initiatives that seem to overlap the area of welfare and are addressed at the life dimension of employee well-being (Zheng et al., 2015) as well as at employees' physical well-being (Grant et al., 2007) and health (Danna & Griffin, 1999): for instance, supplementary pensions and integrative health care insurances. This highlights that for the companies in the sample the boundaries between welfare and well-being are blurred. This is not surprising: welfare services can support people's well-being in its physical and psychological dimensions. From a conceptual point of view, therefore, the well-being concept seems to include welfare, which in general refers to services that benefit people in moments of their lives other than working time.

Among the most appreciated and cited welfare services, there are those oriented towards healthcare prevention and care. It seems that companies end up making up for the critical issues of the public healthcare system: as one interviewee explains, "Among the most important welfare services, started in the 1960s, we have an internal clinic with 15 specialists who visit employees every day and with waiting times of 2/3 weeks. It was and still is among the most popular services offered to our employees. The area of health-related services in general is now back in vogue, it is among the most appreciated also due to the public health crisis".

Among the practices recalled in terms of welfare services, scholastic orientation is also mentioned. This kind of service seems to address the psychological well-being of employees in terms of personal growth (Grant et al., 2007; Zheng et al., 2015).

With specific reference to the psychological dimension of employee well-being, some companies mention remote counseling services, in the case of multinational companies provided through platforms that offer the same service on a global scale but in local languages. In certain circumstances, to address individual cases of psychological discomfort, personalized interventions are performed, aimed at supporting the single person even if the specific need requires a derogation or exception to organizational policies: this approach is represented as an expression of the "culture of personal care".

Focusing on the physical dimension of well-being (Grant et al., 2007), some companies recall the pandemic experience, which necessarily proposed a virtual version of experiences previously carried out in person and opened the way to various types of online services, for instance those dedicated to fitness. In this sense, today companies give employees the possibility of joining virtual gyms through platforms that offer various types of exercises and forms of training, and in their most recent versions integrate also a social dimension proposing games and challenges between employees. Other practices aimed at taking care of the physical dimension of employee well-being include physiotherapy services offered by the company, with a package of free sessions and others accessible at a discounted price, and initiatives aimed at ensuring greater food quality in company canteens.

Interviewees also mentioned various initiatives that could be linked to the general dimension of life well-being, sustaining the general work-life balance and family happiness (Zheng et al., 2015): gifts for births and birthdays, shopping lockers at the office, laundry services, electric charging stations, groups for solidarity purchases.

Some initiatives are focused on two precious resources for employees: time and space. Initiatives linked to better use of time include services for medical visit booking, programs dedicated to parents that offer more time for maternity and paternity in addition to what is already guaranteed by law, more time for people receiving life-saving therapies, and the possibility of exchanging vacation hours between colleagues to help those in need. Regarding space, particular attention is paid to the physical place where the work is typically carried out: the offices. Care for the strictly aesthetic dimension of offices is accompanied by attention to lighting, the choice of colors and the quality of paints, air exchange, and the choice and positioning of plants. Offices should be beautiful to make people come there willingly: to the extent that people can choose where to work due to hybrid work models, the office enters into direct competition with people's homes as a place of work and life. The care due to office spaces is important also because they become the setting for numerous occasions for informal meetings, socialization, and entertainment for employees and management; moreover, bottom-up initiatives are stimulated by setting up informal and welcoming spaces, such as areas for parties and the meetings of employee communities. This seems to address the dimension of social well-being (Grant et al., 2007).

Considering the third research question of this study, that is if and how Italian companies perceive the challenges that remote working creates for employee well-being and how they possibly face these challenges through specific interventions, interviewees appear to be only partially active in addressing them.

Hybrid working is now considered a fact: although each company has adopted different rules or guidelines, remote working is not considered something exceptional but a permanent condition of current work models. For this reason, remote working impacts companies' efforts for the planning and implementation of well-being initiatives in terms of guaranteeing equal access to these initiatives for employees both when working from home and from the office.

Actions explicitly oriented towards the well-being of those who work from home are mainly related to home workstations: coherently with data collected by Hopkins and Bardoel in their qualitative study on Australian managers (2023), also in Italy there is an effort to guarantee that remote workers are well-equipped with monitors, ergonomic chairs and desks, well-functioning Internet connections.

Considering the risk of professional and personal isolation in case of prolonged remote working (Charalampous et al., 2019; Franken et al., 2021; Mazzei et al., 2023a), Italian companies included in this study show to be partially aware of it. Interviewees recognize that well-being is also a product of the interaction with co-workers, so the excessive recourse

to remote working could have a negative impact. To avoid the risk of isolation for individuals and favor organizational integration, companies organize regular meetings in the office for all employees: for example in one company, “We organize a town hall meeting every two months to let them experience the company, trying to tell them things that may be of interest. We create institutional moments of socialization to maintain an open dialogue”. Anyway, other specific practices aimed at reducing the risk of professional and personal isolation of remote workers have not been mentioned, for instance mental health aid or coaching initiatives specifically dealing with remote working issues.

It must be added that a specific concern related to the risk of professional and personal isolation due to remote working has been raised by interviewees regarding newcomers (Mazzei et al., 2023b): interviewees recognize that the intensive use of remote working makes the onboarding process more difficult especially if newcomers are young, because the transmission of corporate values and culture in general can be undermined if the social contact with managers and co-workers is reduced. Therefore in the onboarding period, remote working should be used with caution.

Similarly, considering the risks of workaholicism and of not being able to manage the boundaries between work-life and private life when at home (Biasi et al., 2022; Ferrara et al., 2022; Molino et al., 2020; Spagnoli et al., 2020), some companies recall that they are trying to define some shared rules that allow people to create, and help each other respect, a borderline between work time and personal time: for instance, through the rule “You don’t write to or reply to anyone on the weekend”. No other specific initiative aimed at increasing people’s ability to sustain their work-life balance when at home has been recalled, for instance coaching initiatives proposed to employees with such objectives.

All that said, companies feel anyway the need to assess in a focused way the state of well-being of employees when remote working is in place. Again, consistent with the study conducted by Hopkins and Bardoel (2023), this study confirms that some companies adopt specific tools to monitor employee well-being that help people managers to regularly collect data related to their team members working remotely. Starting from the share of information related to the projects in which employees are involved, these tools allow managers not only to have visibility on the progress of the activities but also to get to know how their employees feel and “how they are doing”. Based on these reports, people managers regulate the dialogue with team members to assess the state of their well-being.

Research limitations. The presented study is at its preliminary stage. The number of companies involved does not allow to make any generalizations regarding the results. Anyway, the data collected through this first exploration can be a base for designing a more comprehensive quantitative study, to investigate more thoroughly and extensively the well-being initiatives and practices implemented by Italian companies, and to obtain a clearer view of how they are dealing with the possible counter-effects of remote working for the well-being of their employees in an era when hybrid work models are becoming permanently adopted.

Managerial implications. The findings of this study underline the importance for managers to look at employee well-being in a multifaceted way. Employee well-being must not be simply reduced to job satisfaction. Of course, it comprises a workplace dimension related to work-related elements such as compensation and benefits or management style: results of this study showed in particular that management style is, according to interviewed managers, the most relevant factor to foster employee well-being among all dedicated managerial initiatives. Other dimensions of employee well-being should then be considered to approach it holistically: in fact, managers should take care of the physical, psychological, life, and social components of employee well-being, implementing practices devoted to sustaining them specifically. The experience of Italian companies included in this study shows a very broad variety of initiatives and practices to deal with these various well-being dimensions. Sometimes these practices overlap with the area of company welfare, especially when services related to employee health and physical well-being are concerned. Finally, this study alerts managers regarding the need to address the challenges that remote working creates for employee well-being. While companies included in this study are rightly concerned about the accessibility of well-being initiatives for employees working from home and/or from the office, specific initiatives for remote workers cannot be limited to sustaining their physical and workplace well-being when working remotely, for instance making them well-equipped in terms of workstation, tools and connections. As literature suggests (Ferrara et al., 2022; Hopkins & Bardoel, 2023; Mazzei, 2023b), companies should pay specific attention to addressing the risks of professional and social isolation, which affect the dimension of social well-being, and the possible difficulties faced by employees to manage the boundaries between work-life and private life when at home. This sensitiveness implies also an increase in the expectations addressed to managers themselves, who in turn are employees and therefore feel needs for their own well-being: an issue that organizations should be aware of.

Originality of the paper. This study explores how Italian managers understand the multifaceted concept of employee well-being and offers insights regarding the initiatives and practices implemented today in Italy to sustain it in its multiple dimensions. Moreover, it explores how Italian companies are dealing today with the challenges that remote working creates for employees. While numerous studies investigated the effects of remote working on employee well-being and productivity during the pandemic, this study contributes to filling the gap of knowledge related to what organizations are implementing to mitigate the negative effects of remote working on employee well-being in the post-pandemic era, when hybrid work models are becoming permanently adopted.

Navigating Transformative Service Research for individual and social well-being: A comprehensive review

MUHAMMAD JUNAID SHAHID HASNI¹ MARIA DELLA LUCIA² ERICA SANTINI³

Abstract

This systematic literature review (SLR) explores Transformative Service Research (TSR) in the Business, Management, and Accounting domains. The primary objective is to discern pivotal factors associated with the conception, design, and execution of transformative services (TSs) to improve individual and social well-being. This research endeavour holds the promise of contributing substantially to enhancing service design principles and practices promoting well-being at different levels and in different domains. Based on a search query string with rigorous inclusion and exclusion criteria, the SLR identified a sample of 188 studies indexed in both Web of Science and Scopus databases. Through descriptive, bibliometric and (manual) content analyses, we depicted the current intellectual structure of the transformative service knowledge domain and the pivotal factor of TSR mainly resulting from healthcare service provision. The manual content analysis confirmed the current literature has addressed significant components and well-being outcomes identified in the TS founding framework, mainly across health services and financial services in urban environments. Tourism and hospitality are emerging and promising TSR fields and heritage, culture and creativity are poorly investigated. Preliminary results indicate that TSR is yet to be fully developed in specific domains and ecosystems, and more research is warranted to shed light on the dynamic realm of transformative services and their contribution outside the traditional domain where TSR developed.

Key words: Transformative services, social value creation, well-being, sustainability, pivotal factors, gaps

Framing of the research. *In the ever-evolving landscape of business and technology, services dominate the value creation processes of our economy and how the needs of our society are satisfied. In this realm, Transformative Service Research (TSR) represents a branch of study within the broader discipline of service research focusing on well-being outcomes related to service (Davis & Pechmann, 2013). TSR has been defined as “the integration of consumer and service research that centres on creating uplifting changes and improvements in the well-being of consumer entities: individuals (consumers and employees), communities and the ecosystem” (Anderson et al., 2011, p. 3). In this literature, well-being encompasses eudaimonic and hedonic dimensions. The former underscores the actualization of one's potential, a concept in line with Sen's notion of quality of life as the advancement of human capabilities and freedoms (Sen, 1999). Hedonic well-being revolves around the notion of pleasure and happiness, as posited by Diener and Lucas (1999).*

Going beyond the centrality of services in the economic exchange, TSR emphasises the “social dimension of value creation” (Blocker & Barrios, 2015, p. 265) within a service ecosystem that interconnects actors at macro, meso and micro levels (Alexander et al., 2018; Rosenbaum et al., 2011). The founding framework proposed by Anderson et al. (2015) conceptualises collective value creation in TSR as a multilevel and multi-stakeholder process identifying the interactions between the service entities (i.e., service employees, service processes, offerings, organisations, and sectors) and the consumer entities - from individuals to collectives and ecosystems - shaping the well-being outcomes for both parties, individually and socially. Compared to aspects and metrics commonly used in service research, the framework emphasises mutual well-being outcomes particularly relevant or innovative in the context of TSR. It focuses on different aspects of eudaimonic well-being including improved dignity and respect, literacy, empowerment, autonomous decision-making, individual and collective health, reduced access, health and well-being disparities, consumer engagement, harmony, and social networks. The framework also relies on subjective components of hedonic well-being encompassing individuals' and people's positive everyday affective state, emotional health and self-esteem such as happiness, satisfaction, and joy (Diener & Lucas, 1999), or their absence such as tension, fear, strain, and stress.

Social value creation by TSR and the multifaceted dimensions of eudaimonic and hedonic well-being associated with TSs intersect significantly with sustainability and the Sustainable Development Goals (SDGs), presenting a comprehensive agenda for fostering a more prosperous, equitable, and resilient future for all, ensuring inclusivity in the journey towards sustainable societies globally and the advancement of human well-being. Consequently, policies and

³ University of Trento
e-mail: erica.santini@unitn.it

strategies focused on well-being increasingly play a pivotal role in facilitating sustainable transitions and stand to gain from dissecting the impacts of TSs across various levels, sectors, and ecosystems. Although the comprehensive scope of the TS framework, spans micro, meso, and macro levels of service provision and consumption, transformative services have primarily undergone examination at the micro-level, particularly within specific sectors like finance, healthcare, and social services (Galeone & Sebastiani, 2021). This concentration underscores untapped potential that warrants exploration and exploitation.

Purpose of the paper. This research aims to investigate the evolution of TSR and conducts an in-depth investigation into TSR seeking to elucidate pivotal factors pertinent to the conception, design and implementation of transformative services improving individual and social well-being. The principal argument posits that an intricate comprehension of TSs holds the potential to substantially contribute to refining service design principles and practices and extend them to domains and ecosystems that could benefit from TSs' pivotal factors, catalysing holistic transformation and healing.

Methodology. The complexity of TSs potentially spanning disparate streams of research literature requires a detailed and nuanced comprehension of antecedent research endeavours about TSR. Similar to prior scholars (such as Caputo et al., 2018; Goyal & Kumar, 2020; Landry & Furrer, 2023) our exploratory research design adopted a Systematic Literature Review based on Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) (Moher et al., 2009) to provide a thorough, unbiased, and replicable synthesis of relevant studies (Donthu et al., 2021; Diaz et al., 2022) ensuring a fine-grained and nuanced understanding of the prior TSR. SLR has been widely employed in service research to systematically identify, evaluate, and critically analyse extant literature (Tranfield et al., 2003; Mariani et al., 2018) on specific and emerging topics such as green purchase behaviour (Sharma et al., 2023) and metaverse (Ritterbusch & Teichmann, 2023), following well-established steps to ensure transparency and rigour in such SLR studies (Madanaguli et al., 2022) (Figure 1).

Figure 1: PRISMA Chart

Source: Authors' elaboration

Aiming to elucidate pivotal factors pertinent to the conception, design, and implementation of transformative services and emphasising their potential intersection with specific domains and ecosystems, the research papers were selected using Scopus and Web of Science (WoS) databases. According to Mongeon and Paul-Hus (2016), the consistent deployment of these databases in prior SLR studies attests to their established reliability and comprehensive coverage. In our investigation, the Boolean operator "AND" has been employed to establish a logical conjunction between the terms transformative, service and well-being, ensuring that only publications containing all three terms are retrieved within the domain of "title, abstract, and keywords" of the publications in the Business, Management, and Accounting domains. The asterisk (*) serves the purpose of accommodating variations in the keywords. Accordingly, the search string was "Transformative servic*" AND "Wellbeing*" OR " Well-being*".

The evaluation of selected studies adhered to predefined criteria, encompassing (a) inclusion of research papers published in peer-reviewed journals addressing TSs, (b) accessibility of research papers through Scopus and Web of Science (WoS) up to November 2023, and (c) inclusion of research papers published exclusively in the English language. A total of 256 studies about TSs and well-being within diverse sectors were initially identified through WoS. Similarly,

252 studies were discovered on Scopus. Merging articles from both databases, Removing duplicates, and including distinct articles through snowball, the initial review phase included 291 studies. By refining the dataset further and reviewing the titles and abstracts, we excluded 103 entries on the grounds of incongruity with the defined scope of research and disparities in research type, encompassing editorial notes, commentary, conference papers, and book chapters.

Descriptive, bibliometric and content analyses through the Bibliometric R package (Aria & Cuccurullo, 2017) and manual content analysis were performed on the final sample, comprising 188 articles. The descriptive analysis explored publication trends, prominent journals, author contributions, and citation statistics. The bibliometric keyword co-occurrence analysis conducted using VOSviewer considered a threshold of at least five occurrences (Beliaeva et al., 2022; Pereira et al., 2022). The content examination through the word cloud showed how often words appeared in the sample (Poyoi et al., 2023) helping to highlight specific areas within research topics or domains based on centrality and density (Scarano et al., 2023). Based on Anderson et al. (2015)' founding framework, the manual content analysis yielded initial insights into the service and consumer entities that impact well-being, as discussed in the existing literature, and identified associated gaps.

Results.

Descriptive analysis. The publication trend over the last 14 years (from 2010 to 2023) years indicates that studies on TSR were first published in 2010 (Ostrom et al., 2010). Over time, the number of publications has notably increased since 2019, with 27 articles in each of the past five years (2019 to 2023). Furthermore, TSR studies have been disseminated across various journals. The *Journal of Services Marketing* has emerged as the leading outlet, with 70 research articles, followed by the *Journal of Service Management* (25 articles), the *Journal of Service Research* (24 articles), and the *Service Industries Journal* (21 articles). Most studies were published by authors (Corresponding authors) from the USA (75 publications), Australia (40), New Zealand (17), United Kingdom (15), and Malaysia (12). American and European countries have gained the top spots in the list of most cited countries. The United States of America stands at the top of the list with 4,441 times cited, and Australia is in the 2nd spot with 1418 times cited. Similarly, Finland (675 times), New Zealand (474 times), and the Netherlands (260 times) have secured the 3rd, 4th, and 5th rank in the list.

Co-occurrence analysis. Six distinct clusters (Figure 2), comprising 116 keywords (out of a total of 1,299) and encompassing 2,492 links reflecting a density of 16.77%, show a relatively dispersed network - the average number of links per keyword (centrality) stood at 21.48. Notably, certain keywords exhibit a higher number of links, particularly transformative service research (114 links), well-being (109), value co-creation (84), dominant logic (81), quality of life (65), service research (63), innovation (59), social support (58), health services (52), and service ecosystem (42). The remaining 12,364 links (comprising 71.26% of the network's total links) demonstrated a link strength lower than 10, with nearly 50% falling below 0.9. The most robust linkages were observed between transformative service research and well-being (65 links), followed by transformative service research and health (22 links), dominant logic and well-being (20 links), value co-creation and well-being (16 links), transformative service research and well-being (15 links), and transformative service research and quality (12 links). These associations are reflected in the keyword clusters: each cluster is identified by a colour and comprises one anchor keyword and associated main keywords, emphasising a specific discourse around TSs (Table 1).

Cluster 1 (Red)'s main theme revolves around the multifaceted aspects of service experience satisfaction affecting people's well-being (Mulcahy, et al., 2021). The cluster recommends analysing customer satisfaction as a crucial factor for evaluating the quality of service experiences, as the latter is crucial to affecting people's general health and quality of life. In addition, it involves exploring the wider effects of service contacts to understand how satisfaction levels and experiences contribute to the overall impact on people's lives. Cluster 2 (Green) focuses on the Health TS Ecosystem, a prominent TS domain. The keyword "dominant logic" clearly suggests a marketing perspective discourse emphasising the centrality of services in the economic exchange process (Danaher et al., 2024). This perspective suggests the interaction between innovation and resource integration to improve the development and sustainability of the health service ecosystem.

Cluster 3 (Navy Blue) is prominent in terms of occurring keywords and linkages and revolves around transformative service research and holistic well-being in people's and communities' lives (Zhang et al., 2023). Within this collective effort, TSR investigates cutting-edge factors for providing TSs. Engagement is a crucial factor focusing on how customer service design may actively include consumers and promote a sense of connection and participation. Happiness emerges as a crucial factor when gauging the emotional and well-being impacts of engaging people in transformative services. Knowledge acquisition is another prominent factor, emphasising how transformative service research helps to produce learning and insights to advance both individual and societal progress

Cluster 4 (Yellow) echoes an emerging discourse in TRS revolving around the service design agenda in tourism for improving societal well-being (Kabadayi et al., 2023). Within a general discussion of how deliberate and careful service design agenda and principles enhance people's and society's well-being, the tourism lens emphasises the potential effects of travel and leisure activities on the well-being of individuals and communities when properly designed.

Cluster 5 (Purple) emphasises the co-creation of transformative services for vulnerable consumers, thus echoing diversity and inclusion issues in different environments. Collaborative processes involving consumers with special needs

Content analysis. The word cloud has shown to be consistent with the thematic clusters of co-occurring keywords. The fifteen keywords that make up 60% of total word frequencies include anchor words such as TSR ($n = 52$, 6%), satisfaction ($n = 44$, 5%), dominant logic ($n = 39$, 4%), impact ($n = 39$, 4%), research priorities ($n = 36$, 4%), and health care ($n = 35$, 4%). The high centrality and density of these themes indicate that they are well-developed and prominent in shaping the transformative service research domain.

The manual content analysis confirmed the current literature has addressed significant components and well-being outcomes identified in the TS founding framework. The main investigated sectors are health services, with the greatest number of papers, financial services, and social services. In relation to the micro, meso, and macro levels, consumer entities are examined at the ecosystem level in retail and food, at the collective level focusing on groups like families, friends, and coworkers, and individual level (Previte & Robertson, 2019). Value co-creation is the process interconnecting both entities investigated the most (Gardiazabal & Bianchi, 2021). Well-being encompasses social outcomes (Rosenbaum et al., 2021) such as preparedness and social cohesion (Cheung et al., 2017) and individual outcomes such as consumer micro-transformations (Gopaldas et al., 2022).

Tourism and hospitality (Gallan et al., 2021; Feng et al., 2023; Galeone & Sebastiani, 2021) are emerging and promising fields in which TSR has been connected to sustainability and sustainable tourism. Gallan et al. (2021) have proposed a novel concept of Transformative Hospitality Services (THS) and viewed hospitality as a potential for holistic well-being transformation. Galeone & Sebastiani (2021) looked at how sustainable hospitality firms enhance well-being in the tourism sector at collective and individual levels. Feng et al. (2023) investigated the impact of employee-customer interaction within hospitality. Heritage (Steriopoulos & Ooi, 2023), culture (Kabadayi et al., 2019), and creativity (Batat, 2021), which are the baseline of the cultural and creative industries and strongly interface with tourism, have been given little attention yet. Steriopoulos and Ooi (2023) focused on the “Melbourne Cup”, discussing how heritage events contribute to transformative experience through consumer transformation, heritage identity, heritage character, and heritage components. Kabadayi et al. (2019) focused on foundational values at the core of the service process, such as organisational culture, to maximise social innovation in service efforts and explained that culture and technology factors challenge the implementation of social innovation in service organisations. Batat (2021) found that creativity and innovativeness during crises are engines of motivation for employees to confront themselves and design a creative and specialised service experience.

Due to the sectors investigated by TSR, most studies are explicitly or implicitly framed in urban ecosystems where usually health, financial and social services cluster. Rural areas are environments missing in the current strand of literature that could benefit from TSR as customers in rural areas have been shown to be more vulnerable than those in urban areas (Ho & Shirahada, 2021). Rural customers engage with service providers more emotionally due to the firm's relationship marketing and its impact on consumer emotional well-being, and compared to urban customers, they are less knowledgeable about services, offerings, procedures, and employees' work habits (Huang & Lin, 2020).

Research limitations. The most frequent keywords appearing in the sample (such as value co-creation, dominant logic, and health care) suggest that the SLR could be refined by considering combinations of these keywords. In addition, the search could be extended beyond the Business, Management, and Accounting domains and to additional databases like EBSCOhost and Google Scholar. Data mining and topic modelling could also be used to compare and complement bibliometric and manual content analysis. This comprehensive approach would provide a large dataset beneficial for leveraging the latest data analysis software, which can help reduce human bias in interpreting literature insights.

Managerial implications. The TSR's pivotal factors and research gaps resulting from the SLR ground and direct forthcoming research undertakings towards domains and ecosystems that deserve and need additional scrutiny, thus contributing to the continued evolution of this dynamic realm. Due to their interactive nature, heritage, culture, creativity, and tourism and hospitality are specific forms of soft services that have been widely recognised to have a positive impact on individual and social well-being through personal development, business innovation and place-making and regeneration. In addition, their spatial agglomeration both in urban and rural areas offers the opportunity to leverage the potential of TS design to improve the quality of life in these ecosystems and address socio-economic and environmental issues through place regeneration initiatives aimed at improving individual and social well-being.

Originality of the paper. TSR offers an innovative perspective to look at service as the fundamental basis of socio-economic interactions and value creation that contribute to well-being and sustainability. Although the concept of value creation in TSR has been recognized for over a decade as a multilevel and multi-stakeholder process, scholarly attention has predominantly been directed towards micro-level analyses. Moreover, this attention has been largely confined to specific sectors where the topic has seen significant development. This study not only identified the research gap and potential of TSR, such as emerging fields where TSR naturally encompasses multiple dimensions, particularly tourism and cultural and creative industries. It also validated the seminal TSR framework's key components and examined the strategic factors used to design and execute TSs that can be extended and adapted across domains and ecosystems where there is a paucity of TS studies. A deeper understanding of the complexities of designing and executing TSs may also help to address cultural diversity, such as the organisational culture, and technological landscape, such as digital transformation.

Le App di food sharing tra benefici individuali e ambientali: ascolto delle conversazioni online degli utenti su Too Good To Go.

SILVIA BELLINI¹ CRISTINA ZERBINI² DONATA TANIA VERGURA³ BEATRICE CECCOLI⁴

Abstract

La perdita e lo spreco di cibo lungo la catena di approvvigionamento sono un problema mondiale, che comporta non solo perdite economiche significative ma anche ripercussioni negative sull'ambiente. La costante crescita del consumo di cibo e la conseguente produzione di rifiuti rendono necessario attuare azioni correttive ad ogni stadio della filiera al fine di frenare lo spreco alimentare. Tra queste, le tecnologie digitali, come le mobile app, possono rappresentare un valido strumento per sostenere le iniziative volte alla riduzione dei rifiuti.

Lo studio analizza il percepito dei consumatori rispetto alle app di food sharing come strumento per ridurre la quota di prodotti invenduti destinati allo smaltimento. Attraverso la metodologia del web listening, sono state analizzate le conversazioni online degli utenti con riferimento all'applicazione Too Good To Go con l'obiettivo di identificare i fattori di utilizzo della stessa e gli elementi di fiducia. I risultati emersi sui fattori edonistici e funzionali relativi alle motivazioni di utilizzo dell'applicazione offrono spunti utili alle imprese che intendono farsi parte attiva nella promozione di comportamenti sostenibili, sviluppando iniziative proprie oppure attivando collaborazioni con app consolidate come quella analizzata.

Key words: *Too Good To Go; web listening; spreco alimentare; sostenibilità; applicazioni mobile.*

Framing della ricerca. *Con l'aumento della popolazione mondiale, la gestione dei rifiuti alimentari è emersa come una delle sfide principali del XXI secolo, a causa della prevista crescita del consumo di cibo e la conseguente produzione di rifiuti. Non solo, negli ultimi decenni, il tasso di crescita della produzione alimentare ha superato quello della popolazione globale (Holt-Giménez et al., 2012) con un ovvio risultato: la perdita e lo spreco di cibo lungo la catena di approvvigionamento. A livello mondiale, dal momento del post-raccolto all'arrivo nei punti di vendita, questa perdita è pari 14% del cibo prodotto, per un valore pari a 400 miliardi all'anno (FAO, 2019). A questo si aggiunge un ulteriore 17% che viene sprecato nelle fasi finali della filiera: punti vendita al dettaglio e consumatori finali (UNEP, Food Waste Index 2021). Nei Paesi dell'Unione Europea, la quantità di cibo sprecato ogni anno ammonta a quasi 59 milioni di tonnellate, pari a 131 kg di rifiuti per persona (Consilium Europa, 2023).*

L'UE definisce gli sprechi alimentari come "food and inedible parts of food removed from the food supply chain to be recovered or disposed of (including -composted, crops ploughed in/not harvested, anaerobic digestion, bioenergy production, co-generation, incineration, disposal to sewer, landfill or discarded to sea)" (UE FUSIONS 2016).

Per frenare lo spreco alimentare è necessario attuare delle azioni correttive a ogni stadio della filiera, dalla produzione alla vendita dei prodotti finiti, passando per la trasformazione, lo stoccaggio, la manipolazione e il trasporto. Le Nazioni Unite mirano a dimezzare lo spreco alimentare nei punti vendita al dettaglio e presso i consumatori finali entro il 2030 (ONU, 2015), in linea con gli Obiettivi di Sviluppo Sostenibile (SDG 12.3). Anche nell'UE, sempre più orientata verso un'economia circolare, la riduzione degli sprechi alimentari è un obiettivo prioritario (CE, 2015). I Paesi dell'UE si sono impegnati a ridurre del 50% i rifiuti alimentari pro-capite, sia a livello di vendita al dettaglio che di consumo, entro il 2030, nonché a diminuire le perdite alimentari lungo l'intera filiera (CE, 2018). L'impatto di questo spreco ha anche ripercussioni a livello ambientale, oltre che economico, contribuendo alle emissioni di gas serra e alla riduzione dell'instabilità climatica (FAO, 2022).

L'economia circolare (EC) è un modello di produzione e consumo che permette di separare la crescita economica dalla pressione ambientale (Hofmann, 2019), promuovendo una prospettiva riduzionista legata al miglioramento delle

pratiche di gestione dei rifiuti, sostenendo modelli di riciclo, recupero e riutilizzo dei beni (Ghisellini et al., 2016). Si tratta, quindi, di un modello la cui applicazione può contribuire alla riduzione degli sprechi alimentari, andando ad agire sulle abitudini e i comportamenti di consumatori e retailers (Morone et al., 2018). Numerose sono le iniziative proposte in tal senso, come le guide per la preparazione dei cibi (Kim et al., 2020) e sulle modalità di riciclo dei rifiuti (Lang et al., 2020) e le raccomandazioni sulle abitudini di stoccaggio domestico (van Holsteijn e Kemna, 2018). Le tecnologie digitali, come le mobile app, possono rappresentare un valido strumento per sostenere le iniziative volte alla riduzione dei rifiuti alimentari (Schanes et al., 2018; Vo-Thanh et al., 2021), spingendo i consumatori verso uno stile di vita più sostenibile. Tra queste, sono state sviluppate piattaforme per mettere in contatto i consumatori o le imprese locali per condividere le rimanenze di cibo (Zurek, 2016), applicazioni che propongono quotidianamente ricette per cucinare gli avanzi alimentari (Schanes et al., 2018), oppure per mettere in contatto consumatori con supermercati, bar, ristoranti, panetterie, pasticcerie per l'acquisto a prezzi ridotti di cibo avanzato a fine giornata (Apostolidis et al., 2021). Too Good To Go (TGTG) è una mobile app che rientra in quest'ultima fattispecie, una "anti-food waste mobile app" che "consente di salvare il cibo invenduto da un triste destino" (toogoodtogo.com). L'obiettivo di TGTG è quello di connettere i consumatori con piccole e grandi attività o aziende che altrimenti avrebbero prodotti invenduti destinati allo smaltimento. Un'applicazione di food sharing come questa, dove ciascun esercente può caricare i propri prodotti invenduti e ciascun consumatore può accedere alle offerte proposte, è una soluzione win-win-win perché costituisce un vantaggio sia per i consumatori, sia per gli esercenti sia per l'ambiente.

Vo-Thanh et al. (2021) hanno studiato, attraverso interviste semi-strutturate, la capacità dell'app TGTG di fungere da catalizzatore di un'iniziativa con finalità sociali e di sostenibilità. Gli autori hanno dimostrato i valori sociali, funzionali ed emotivi rappresentano i principali fattori di successo dell'app, grazie ai quali è possibile ridurre gli sprechi alimentari e i connessi danni sull'ambiente. A ciò si aggiunge il fine sociale di consentire a chiunque di accedere a cibo di qualità a prezzi accessibili. Anche Lewandowski (2023) ha dimostrato la capacità di TGTG di contribuire efficacemente alla riduzione degli sprechi alimentari. La caratteristica interessante di questa app è la sua prospettiva win-win-win poichè le ricadute sono positive per il consumatore, che riesce ad acquistare cibi di qualità a prezzo scontato, per i rivenditori, che vendono prodotti che altrimenti verrebbero buttati, per l'ambiente, grazie alla riduzione degli sprechi. Nonostante il rilevante successo di TGTG e la sua provata efficacia nel contribuire fattivamente alla sostenibilità ambientale e sociale, le ragioni che spingono i consumatori ad utilizzare l'applicazione e gli elementi di soddisfazione e insoddisfazione in seguito al suo utilizzo, non sono ancora state studiate. Individuare i fattori critici di successo di TGTG potrebbe fornire utili suggerimenti alle imprese che intendono contrastare lo spreco alimentare attraverso strumenti digitali, ma anche tradizionali, nella prospettiva di ampliare il target raggiungibile aumentando di conseguenza la portata dei benefici ottenibili in termini di sostenibilità.

Obiettivo. Il presente lavoro intende analizzare, attraverso la metodologia del web listening, il vissuto da parte degli utenti dell'app TGTG. In particolare, lo studio si è posto l'obiettivo di identificare i fattori che spingono all'utilizzo (o non utilizzo) dell'applicazione e gli elementi di fiducia/sfiducia verso la stessa. L'interesse verso TGTG si riconduce alla sua diffusa presenza nel mercato e al suo ruolo di app di riferimento per la riduzione del cibo invenduto. Si tratta della più grande piattaforma B2C contro lo spreco alimentare, che si colloca al settimo posto tra le applicazioni per il cibo e le bevande più scaricate al mondo. Lanciata nel 2016 e attiva in 17 Paesi tra 2 continenti (Europa e America), TGTG vanta una community composta da oltre 8 milioni di utenti registrati e più di 142.000 partner commerciali. Ad agosto 2023, l'azienda ha dichiarato di aver contribuito a salvare più di 250 milioni di pasti dal rischio di andare sprecati, l'equivalente di 625.000 tonnellate di CO2 evitate (Too Good To Go, 2023).

Metodologia. Il disegno di ricerca ha utilizzato un approccio metodologico mixed-methods che ha combinato l'analisi testuale quantitativa con quella qualitativa (Andreotta et al., 2019). L'analisi è stata effettuata tramite la Blogmeter Suite, una piattaforma di web e social intelligence che consente di raccogliere e analizzare il conversato degli utenti su social media e altre piattaforme del web (Facebook, Twitter, Instagram, YouTube, Tik Tok, Twitch, forum, blog, notizie e siti di recensioni di app), attingendo a un database di oltre 2 miliardi di documenti, raccolti sia dalle interfacce di programmazione delle applicazioni (API) ufficiali dei social network, sia dai crawler proprietari di Blogmeter. Sono stati analizzati tutti i testi tracciabili e leggibili che contenevano almeno una parola chiave tra quelle selezionate per l'analisi: "toogoodtogo", "2good2go", "too good to go", "tu good tu go", "two good two go", "too good tu go", #toogoodtogo. Il sottoinsieme complessivo dei dati estratti con queste query è stato ripulito manualmente per prendere in considerazione solo le occorrenze delle parole chiave che riguardavano i temi e l'app oggetto di analisi. Le metriche prese in considerazione per l'analisi quantitativa sono state: total messages, mentions, engagement e positive/negative sentiment. Il corpus è stato organizzato e suddiviso in lotti di keywords. Sono stati identificati i topic rilevanti per la ricerca – l'app TGTG e i topic sostenibilità/ambiente, fiducia/fedeltà, spreco alimentare, risparmio/costo – in base ai quali sono stati estratti sottoinsiemi di dati per un'analisi qualitativa più accurata.

Risultati. Una prima riflessione emerge osservando il cloud dei termini e degli hashtag impiegati dagli utenti per discutere dell'app (Figura 1).

per i quali si può facilmente trovare una soluzione e che non mettono certamente in discussione l'identità dell'app e la sua mission.

Il successo di TGTG lo si deve alla sua capacità di soddisfare le aspettative che gli utenti hanno nei confronti delle app sostenibili. Il beneficio collettivo è senz'altro importante, ma si affianca al beneficio individuale ricercato attraverso il risparmio e la gratificazione per aver concluso "un affare". Analizzando, infatti, i topic più rilevanti associati alle app sostenibili (Figura 3), il tema, generale, dello spreco alimentare è il più menzionato (34%). Esso viene associato in maniera inequivocabile all'app TGTG, ritenuta efficace nel convincere della sua promessa di lotta allo spreco alimentare. Emerge, poi, l'importanza del risparmio/costo (29%), che si conferma, dunque, un essenziale driver di utilizzo delle app di food sharing, che vengono percepite come non più funzionali quando l'affare viene meno.

Figura 3 – Topic associati all'app TGTG

Fonte: nostra elaborazione

La sostenibilità è una tematica importante (23%), ma secondaria rispetto al fattore economico. Sebbene gli italiani riconoscano nelle app il merito di rendere possibili comportamenti più sostenibili, la centralità della sostenibilità passa attraverso il benefit del prodotto e vantaggi immediatamente tangibili: possibilità di risparmiare su acquisti abituali, facilità e sicurezza d'utilizzo.

Il tema che segue è quello della fiducia/fedeltà (11%), menzionato sia con riferimento alla facilità e sicurezza d'utilizzo sia alla fiducia nella promessa di sostenibilità. Questo trova riscontro nell'analisi molto positiva del sentiment dei contenuti riferiti al tema della fiducia nei confronti dell'applicazione, a riprova della credibilità che quest'ultima è riuscita a conquistare (Figura 4).

In sintesi, le app di food sharing – e, in particolare, Too Good To Goo – sono considerate un buon strumento per contribuire al rispetto dell'ambiente, ma solo a condizione che siano anche sostenibili dal punto di vista economico: la promessa di sostenibilità deve essere accompagnata da effettivi vantaggi in termini di costo e da un'esperienza di fruizione semplice, piacevole e divertente.

Discussioni e implicazioni manageriali. La ricerca fornisce utili spunti alle imprese che intendono farsi parte attiva nella promozione di comportamenti sostenibili, sviluppando iniziative proprie oppure attivando collaborazioni con app consolidate come quella analizzata. L'insight a nostro avviso più interessante emerso dai risultati della ricerca riguarda la multidimensionalità delle motivazioni di utilizzo dell'applicazione: da un lato, la dimensione individuale (risparmio economico) convive con quella collettiva (beneficio per ambiente e società); dall'altro lato, i benefici funzionali (facilità d'uso) si uniscono a quelli edonistici (scoperta e divertimento).

L'eterogeneità dei benefici ricercati trova spiegazione nella natura stessa delle scelte sostenibili, che sono di per sé "intertemporali", ovvero richiedono un sacrificio oggi per un beneficio futuro, che non è necessariamente garantito né individuale (Bellini, 2023). La presenza di benefici non immediati e disallineati può costituire un disincentivo ad assumere comportamenti sostenibili, a maggior ragione se questi richiedono sacrificio e se non hanno una contropartita vantaggiosa per l'individuo. Per favorire l'engagement e aiutare l'individuo nel mantenere saldo il comportamento nel lungo periodo, è opportuno trovare il giusto equilibrio tra benefici collettivi e individuali. La leva del prezzo, quindi, rappresenta un buon rinforzo a sostegno delle iniziative che intendono stimolare l'individuo a farsi parte attiva nella sostenibilità ambientale e sociale.

Il successo di TGTG lo si deve alla sua capacità di soddisfare le aspettative degli utenti nei confronti delle app sostenibili in relazione alla presenza di benefici immediatamente tangibili quali la possibilità di risparmiare su acquisti

abituale, la facilità e la sicurezza d'utilizzo. Bisogni individuali e collettivi convergono, così come elementi funzionali ed esperienziali. La dimensione edonistica legata alla scoperta di nuovi prodotti e alla ricerca di nuove esperienze culinarie alimenta l'engagement degli utenti e favorisce quello spirito di aggregazione e appartenenza che rappresenta una delle chiavi di successo delle iniziative nel campo della sostenibilità.

La reputazione e la credibilità di TGTG nel campo della sostenibilità deve essere tenuta in considerazione da parte delle aziende che intendono farsi parte attiva in questo ambito stringendo collaborazioni e partnership esterne. È il caso, per esempio, delle numerose aziende della grande distribuzione alimentare che si stanno impegnando sul fronte dello spreco alimentare attraverso iniziative proprietarie ma anche accordi con TGTG. Contare su un partner riconosciuto e affidabile accresce la reputazione anche dell'insegna e può rappresentare un elemento di scelta del punto vendita.

La sostenibilità è un terreno molto complesso che deve essere affrontata in maniera sinergica da tutti gli operatori della filiera nella consapevolezza che la promozione dei benefici collettivi passa anche attraverso una dimensione individuale e utilitaristica di cui occorre tenere conto.

Limiti della ricerca. La presente ricerca costituisce il primo step di analisi all'interno di un più ampio progetto di studio volto a individuare i driver di utilizzo delle app sostenibili, nonché le conseguenze percepite che ne derivano. Proprio per questa ragione, si possono individuare alcune limitazioni che si intendono colmare attraverso la prosecuzione della ricerca. Innanzitutto, il focus è stato posto su una specifica app - TGTG - ma dovrebbe essere esteso ad altre applicazioni, anche in contesti diversi da quello alimentare, al fine di far emergere gli elementi di successo. In secondo luogo, per consolidare i risultati ottenuti da questa prima ricerca, sarebbe necessario svolgere un'indagine quantitativa che permetta di misurare gli elementi emersi e il loro impatto sul comportamento del consumatore.

Originalità. Nonostante l'ampio successo riscosso negli ultimi anni da TGTG, oggi considerata l'app di riferimento per la riduzione del cibo invenduto, nessuno studio in letteratura ha indagato i driver che spingono i consumatori ad utilizzare l'applicazione e, soprattutto, gli elementi di soddisfazione e insoddisfazione che ne derivano dal suo utilizzo. Il presente lavoro colma tale gap e lo fa utilizzando la metodologia di raccolta dati del web listening: l'analisi del conversato in rete e, quindi, del vissuto raccontato dagli utenti, ha permesso di individuare i fattori critici di successo, nonché gli elementi di fiducia verso l'applicazione.

Ringraziamenti. Gli autori ringraziano l'azienda Blogmeter, gruppo Shibumi, che ha raccolto ed elaborato i per il seguente studio.

Well-being as a key for sustainable and long-term oriented management

DARIO NATALE PALMUCCI¹ GABRIELE SANTORO²

Abstract

While digitalization and hybrid work models have undoubtedly brought positive impacts to organizations and individuals' performance, they have also posed challenges to psychological safety. In fact many employees, particularly knowledge workers, struggle to navigate the intrusive digital professional reality, leading to increased work-related stress. Although the attention on the consequences of this new form of work-related stress has increased, prior research has primarily concentrated on examining these facets through the perspectives of stakeholders taken singularly (such as psychologists solely, HR practitioners only or employees alone). In contrast, this work delves into a range of viewpoints from various stakeholders together, providing a more comprehensive understanding. As such, the insights garnered from this study were derived from a blend of literature review and interviews conducted by the researchers with various stakeholders together (HR practitioners, employees and psychologists). From a theoretical point of view, the study adds to the literature shedding light on consequences of uncontrolled hybrid work models and technology advancements (in particular negative effects on employees' psychological wellbeing). In addition, this work also offers practical examples, insights and actionable tips derived from practitioner experience, emphasizing the importance of leaders' awareness in managing performance and ensuring psychological safety. For all these reasons this piece of work can function as a roadmap for creating and putting into effect institutional regulations, organizational policies, and procedures that promote telework practices beneficial to the health and wellness of workers.

Key words: Management; organizational wellbeing; teleworking; digitalization; work-related stress; digital wellbeing

Framing of the research. This work is focused on organizational wellbeing practices in the actual post-covid-digitalized era and it is anchored to the general stream of wellbeing, which conceptualization varies in meaning between and within disciplines (Ronen and Kerret, 2020). In particular, regardless its definition, wellbeing (and wellbeing at work) is considered always more relevant and both the scientific community and institutional bodies are looking at wellbeing as a key for sustainable development (Frey, 2018). In other words, occupational health means to ensure safe conditions for people's well-being in the workplace (Battaglia et al, 2020) and the necessity of an in-depth analysis on this topic springs from the transformative shift we have witnessed during the pandemic when organizations resorted to technology and telecommuting to sustain their operations (Mariani et al., 2023; Andrulli and Gerards, 2023). Remarkably, these novel work modes not only persisted beyond the crisis but have become central to contemporary work dynamics in the post-Covid landscape (Kokshagina and Schneider, 2023). However, despite the positive impact of digitalization and hybrid work models on organizational and individual performance, concerns are mounting regarding employee and people well-being (Shukla et al., 2024) which must remain the ultimate goal of sustainable development (Helne and Hirvilammi, 2015). In fact, if from one hand relevant contributions indicate that employees who dedicate part of their time to remote work often receive more positive performance evaluations from their supervisors (Choudhury et al., 2022), conversely there is compelling evidence indicating a notable decline in workers' health, particularly in their mental well-being (Marino and Capone, 2021), along with the increasing challenge of maintaining clear boundaries between home and work environments. This blurring of boundaries has significantly hindered employees' ability to disconnect (Campbell and Gavett, 2021). Here the framing of this research comes into play: if according with previous studies organizational wellbeing is defined as "the whole of cultural, processes and organizational practices that light up co-working life, promoting, maintaining and improving the physical, psychological and social wellbeing of work communities" (Sancassiani et al., 2015), then wellbeing is in danger and recent literature sustains that after pandemic more and more workers struggle with stress stemming from information overload and constant notifications (Parra et al., 2022; Mariani et al., 2023). Considering what said, attention on this area has grown, with researchers and professionals always more focused at exploring all sides of the hybrid work models: both opportunities and risks. However, there is still a gap and in particular it refers to the fact that despite the increased attention on the consequences of this new form of work-related stress, actual studies are unable to provide a comprehensive perspective as they are primarily focused on examining these aspects from the standpoint of individual stakeholders, such as psychologists only, or HR practitioners

solely, or employees exclusively. In contrast, this exploratory work explores a range of perspectives from various stakeholders together (including HR professionals, employees and psychologists), leading to a more comprehensive understanding.

Purpose of the paper. This work in progress is a part of a wider project that aims to shed light on the matter of organizational wellbeing in light of the revolutionary changes on remote work modalities brought from the *global Covid-19 crisis*. In fact, following the public health emergency, organizations have increasingly embraced novel technologies and alternative work arrangements such remote working (Capo et al., 2022). This transition has impacted employee performance and organizational objectives from one side, from the other side these significant shifts have also resulted in heightened work-related stress for employees who struggle to manage the pervasive digital work environment effectively. For this research endeavors to thoroughly investigate organizational well-being in the post-COVID era by gathering perspectives from various stakeholders. The objective is to present tangible examples and actionable solutions that emerging leaders can utilize, thereby fostering a comprehensive grasp of the topic. To summarize, if as previously mentioned organizational wellbeing is defined in terms of practices promoting, maintaining and improving physical, psychological and social wellbeing (Sancassiani et al., 2015), then these three relevant aspects must be carefully investigated and thus represent the main objective of the study. This research also aims to provide managerial implications that actual leaders should consider, contributing to a better understanding of the topic.

Methodology. For this study, a qualitative methodology involving interviews with diverse stakeholders is employed. This approach is chosen based on prior research affirming the effectiveness of qualitative methods in exploring wellbeing (Dawes et al., 2021). In addition to delve deeper into these phenomena and in order to offer a more holistic understanding of the factors affecting employees' wellbeing, our study adopts a diverse sample to explore diverse viewpoints from both internal and external stakeholders. Internal stakeholders refer to two categories of organizational actors daily dealing with the constraints of remote working modalities (thus first HR professionals allowing/defining rules of these teleworking modalities in their organizational contexts, second employees who direct experience the effects of the hybrid working solutions). External stakeholders instead refer to those professionals not directly integrated in the organizations but that assist knowledge workers and support them externally in the actual digital overstressed reality (thus psychologists). This approach, drawing from similar methodologies used in previous studies (Todisco et al., 2023), aims to maximize exploratory impact (Gustafsson, 2017) of the work. In other words, the findings have been identified by mixing literature findings with qualitative data obtained by the researcher conducting interviews with different stakeholders mentioned above. With regard to the methodology then it is also important to remark that the paper is based on a theory synthesis perspective (Jaakkola, 2020) supported by qualitative evidence following Saunders and Townsend (2016) and Palmucci (2023). In particular, 16 participants from different organizational contexts have been interviewed as previously done in other exploratory studies (Bresciani et al., 2016). Thus the sample represent different industries and services and the interviews comprised two distinct parts. In the initial part, participants were asked to share in general their personal experiences with telecommuting methods and the adoption of technology within their specific settings. More in the details, according with organizational wellbeing definition of Sancassiani et al., (2015), that clearly refers to three aspects of wellbeing (i.e. physical, psychological and social), they were encouraged to express their concerns on their daily practices and if they are experiencing work-related stress. Subsequently, in the second part, participants were asked to propose potential remedies to avoid negative consequences. Concluded the data gathering, the information obtained were later arrayed following the Gioia's technique (Gioia et al., 2013) which builds upon the grounded theory and ensures methodological accuracy when using qualitative approach. By using this method, data are analyzed in first-order concepts, then grouped into second-order themes considering similarities, and then finally refined into aggregate theoretical dimensions.

Results. As mentioned, this study is a work in progress and part of a wider project. This means that the ones obtained are ongoing findings and other interviews will be conducted in the coming period. However, throughout the interviews carried out till now, participants underscored several benefits linked to remote working and technology but, as expected, the majority of the participants are facing significant challenges and expressed concerns about their psychological safety. The main results of the analysis performed with Gioia method and considering definition of wellbeing (Sancassiani et al., 2015) are summarized in the 3 aggregate dimensions discussed below:

- **Physical wellbeing=** On a physical level, participants reports several negative effects as eyes problems (because of the increased time spent in front of screen), sleep disorders (one participant said: "I read e-mails till the very last minutes before going to sleep and consequently during the night I am not able to stop thinking on tasks"), obesity and sedentary lifestyle (because of the decrease in movement even just moving from one's desk to that of a colleague for a meeting) joint pain at neck and back (because of un-appropriate work station used at home);
- **Psychological wellbeing=** On a psychological level, participants reported several psychosomatic symptoms caused by continuous workloads. In particular, interviews with psychologists reveal a significant increase in psychological issues within their patients (e.g., anxiety, addictions, loneliness, burnout cases, etc.). Furthermore, one psychologist interviewed noted a doubling in burnout cases since the pandemic began affirming that workers find difficult disconnecting from work, they are becoming addicted to constant digital communication.
- **Social wellbeing=** at a social level, participants are reporting the "blurring of personal and professional boundaries". In particular, working from home blurs the lines between personal and work life. In fact, while going to the office can provide a break from family and emotional issues, remote work alongside family members can lead to constant overlap between these spheres. This ambiguity makes it difficult to differentiate between work and family time. As a result and paradoxically then, despite the initial intention in introducing remote working practices was to increase work-life

balance for employees (Kokshagina and Schneider, 2023), we are now assisting to a decline in work-life Balance among employees remote workers because working in shared spaces with family members (like kitchens or relaxation areas) is disrupting the necessary boundary between work and personal life and is increasing stress experience instead. In addition, many many remote workers feel pressured to be constantly available online, leading to extended working hours beyond the designated schedule. Fear of not being seen as active online can exacerbate this tendency, as expressed by one participant who felt “guilty for disconnecting during lunch breaks”.

Research limitations. This study is not without limitations. First the limits refer to the approach adopted. It is to say that to prevent further segregation of managerial knowledge and to increase the validity of the results obtained, it remains essential to gather more data and perhaps by adopting diverse additional modalities of data gathering (e.g. quantitative data, etc.). Considering what said, researchers ought to integrate these findings should utilize different methodologies to advance knowledge in this topic. Also as already mentioned, this study is a work in progress and part of a big and wider project, therefore more data gathering would help in the next phase to better understand the phenomena both at theoretical and a managerial level. Furthermore, it's essential to address discrepancies between internal (HR professional and employees) and external (psychologists) stakeholders' perceptions of organizational efforts towards stress alleviation. Internal stakeholders may feel unsupported in comparison to external perceptions. On this regard, more categories can be added to the sample (as internal organizational counsellors or external consultants and coach) in order to have a clearer picture of the subject investigated and consequently increase the generalizability of the findings.

Managerial implications. In essence, the research contributes to both theory and practice by analyzing the risks for employees associated with the abuse of technology and new working modalities. The information gathered from various stakeholders as HR professionals, employees and psychologists, provide a comprehensive view of real-world scenarios. From a managerial point of view, given the imperative digital transition that decision makers must lead, alongside the shift from in-person work models to remote modalities (Fayard et al., 2021), seems to be clear that future leaders should demonstrate fully openness and adaptability to welcome these necessary epochal changes. A crucial aspect, therefore, concerns in spreading awareness within organizational contexts and departments regarding how much important is not to ignore the dynamics described. This implies promoting training programs focused on digital well-being courses able to encourage the implementation of work routines and best practices for preserving the psychological safety of workers. Considering what said, remedies and solutions proposed are the following:

- **Re-defining Policy and Rules** = First of all, as expressed from some of the interviewees, “it is not possible looking at the future with the “lenses of the past”. In other words, it is primary important to be aware of the epochal change and wear new lenses when disorientation dominates (Baccarani and Golinelli, 2011). Therefore, policy makers should solicit for example a “right to disconnect” in order to preserve the essential boundaries between personal and professional life. As we are assisting, employees fell they have no freedom to disconnect from work responsibilities, then organizational leaders need to intervene and establish clear working rhythms. Another good example of tentative to look at the future with new lenses is to completely rethink the annual and sick leave policies. In fact, traditional leave policies no longer suffice in the current digitalized era. Remote work complicates the process of requesting sick or annual leave (one participant said: “often, if people are sick, they do not ask for sick leave but they keep working from home”, leading to imbalances and increased stress. Reevaluating these policies is crucial to adapt to the post-Covid digital landscape. Another important aspect which must be re-defined is relative to the shaping of organizational cultures and communities which is jeopardized from remote working modalities. On this regard, HR departments should invest in organizing more retreats and outdoor activities to foster team building, collaboration and workers' alignment with organizational goals. This is particularly important for the onboarding of new hires who are finding difficult interacting with colleagues and build relationships effectively with remote working;
- **Learning and development training programs**= considering the constrained highlighted and in order to proactively deal with these issues, organizations (and in particular HR departments) should work in implementing revised safety training programs. This new digital well-being training could be essential for employees and could help them in integrating mental health measures into daily routines, such as managing notifications and also promoting a digital detox Culture (encouraging for example periods of disconnection from digital devices). Also, learning and development training programs should focus on the development of new leadership models. This is important for both top management (whose sponsor is fundamental to support these initiatives) and first line supervisors to actively lead the digital transition. In other words, leadership awareness is crucial for taking a proactive approach, monitoring employees' well-being and use effective communication skills for managing remote teams. This last aspect is also fundamental: providing training to supervisors (and thus enhancing their leadership soft and communication skills) is essential to help in maintaining motivation and productivity among remote workers. This means embracing a new concept of leader who needs to adopt an innovative and people-oriented approach, prioritize the well-being of employees while driving digital transitions. Proactive leadership involves anticipating/addressing challenges and ensuring a supportive work environment for all team members.

Originality of the paper. This research holds relevance not just for supervisors contending with these challenges in their daily work, but also for the scientific community aiming to enhance their understanding of the matter of wellbeing. In fact, while the focus on the ramifications of this emerging type of work-induced stress has grown, previous research has largely focused on analysing these aspects from isolated stakeholder's points of view and perspectives (e.g. solely psychologists, or employees only, etc.) whereas this study explores diverse viewpoints from different organizational actors

offering a more holistic understanding. Thus, aligning with the exploratory essence of the study and in order to have a more comprehensive perspective, the insights obtained with this study were gleaned through a combination of literature review and interviews conducted by the researcher on a diverse sample composed of HR managers, senior managers, subordinates, organizational counselors, psychologists, consultants, and coaches. In addition, as also done in previous studies (Bresciani et al., 2016), the diverse sample of participants interviewed represents different work environments across different sectors (increasing the generalizability of the findings) in diverse domains. As said, the insights derived from this study result from a combination of literature review and interviews conducted as also done in previous studies (Ravazzani et al., 2021) that focused on qualitative data and documentary analysis for analyzing practice developments. To conclude, like significant evolutionary processes in history, 2020 will be etched in memory as a pivotal juncture in the evolution of organizational wellbeing and it is primary fundamental to increase the knowledge on these paradigmatical changes and the risks associated.

The role of the enterprise in the pursuit of the well-being for citizens and society. The contribution of the Italian Schools of Enterprise Economics and Management

SILVIA BRUZZI¹

Abstract

The paper presents an ongoing research project that, starting from the crisis of the globalisation process and the liberist model, aims to revitalize the liberal thought, which has flourished in the field of Enterprise Economics and Management. Through a robust research methodology, based on both a systematic literature review and the involvement of key stakeholders in the Italian economic system, the research aims to enhance the contribution that the different Italian Schools of Enterprise Economics and Management in the second half of the XX century have made to the construction of the capitalist model that gave rise to the Italian economic miracle, also participating in its government. The research proposal suggests that as in the post-World War II period the Academy contributed through thought and action to the construction of the model on which the Italian economic miracle flourished, today we are called on to contribute to the construction of the new European and Italian model of development and growth.

Key words: *Enterprise Theory; European Model of Development and Growth; Liberal Thought; Well-being; Society*

Framing of the research. *The topic of the SIMA 2024 Conference presents a cultural opportunity of historic significance. Addressing the contribution of enterprises to the well-being of citizens and society places our discipline amidst the major crisis that Western economic systems and the economic models prevailing in recent years have been undergoing. The crisis is evident: disorders, resource shortages, inflation, and humanitarian emergencies have marked Europe and the United States for some years now. Institutions seemed incapable of effectively addressing this crisis, lacking a strategic vision that could offer peaceful solutions and stability. This vacuum is filled by some large multinational corporations, often owned by a few investment funds, which thereby exert their influence in markets and beyond. Medium, small, or less structured enterprises, which grapple with crises daily, are among the victims of this disorder. Consequently, the purchasing power of citizens declines, society experiences increasing levels of poverty, and growth prospects are slow to emerge.*

This crisis is an expression of the globalisation that characterised the end of the 20th century and the early years of the 21st century. With the process of globalisation, markets have transcended State boundaries, and multinational enterprises have been able to exploit the advantage of operating in an unregulated global environment. Through globalisation, liberalism has gradually been supplanted by liberism (Croce and Einaudi, edited by Solari, 1957). According to liberal thought, market actions must be regulated by the State; however, with the erosion of national borders, the market has been able to rapidly expand, exploiting and generating various gaps. Consequently, States have become incapable of regulating economic actions at the international level, resorting to cooperative solutions if not integration (as in Europe) at the regional level.

As the globalisation-liberism binomial declines, new balances are emerging. For example, the cohesion between certain countries, notably the BRICS, has accelerated, with the growth of member countries and the deepening of economic agreements among them.

For Europe it is about reinventing the European development and growth model. This was said in April 2024 in Brussels by Mario Draghi, who has been charged by the European Commission to prepare a Report expected after the European Parliament elections on the future of European competitiveness. Draghi argues that the European development model has dissolved, that the European approach to competitiveness undermines the European social model, and it is therefore necessary to reinvent a different way to grow. He highlights three emerging common threads, which have a lot to do with our discipline and the theme of the conference. The first is enabling scale; the lack of enabling scale penalizes our ability to compete because we fail to bring innovations to the market stage (this is what has been called by the European Commission in 1995 Green Paper on Innovation the European paradox, which is still unresolved). The second thread is providing public goods (just think of infrastructure barriers to development). The third thread is securing the supply of essential resources and inputs. The issue has a lot to do with energy for example, but other commodities also

¹ Università di Genova
e-mail: silvia.bruzzi@unige.it

meet our basic needs. For these reasons Draghi is now preparing a European model of development and growth radical change proposal (Euractive Italia, 2024; Sole 24 Ore, 2024; Draghi, 2024).

Also within the framework of Draghi's speech is Enrico Letta's report, which is the first document released on the specific topic of the European Single Market, considered a pillar of the European model. Letta argues that "several factors call for updating the cardinal points of the Single Market, aligning them with the European Union's new vision for its role in a world that has grown "larger" and undergone significant structural transformation" (Letta, 2024, p. 4).

This certainly involves the enterprise, its role, and its management, which calls the Academy to deep scientific reflection.

Today we are experiencing a situation like that of the post-World War II period. This research seeks to highlight that just as then some scholars in our discipline, acting as civil servants, participated in the construction of the socio-economic development model of the time, creating the economic miracle and the conditions of prosperity that we still partly enjoy, today, reconnecting with our academic tradition, we are called for making a tangible contribution to the designing of a new, original model of development and growth.

Purpose of the paper. The purpose of the research is twofold. Firstly, the research aims to highlight the characteristics of the XX century American, European, and Italian liberal models, emphasizing their strengths compared to the liberist model upon which the process of globalisation, today in crisis, was based.

Secondly, the research seeks to underscore the role played by Italian Schools of Enterprise Economics and Management, operating autonomously yet synergistically, in shaping the Italian economic miracle of the 20th century. The thesis proposed in this research is that the current crisis offers an opportunity for a substantial reflection on the role of the enterprise in society, grounded in the teachings of past Masters.

As several scholars in Enterprise Economics and Management did in the first development cycle, the research aims to provide an answer to the current real problems that European and Italian enterprises are facing, to create the conditions for sustainable competitiveness and the well-being of society.

Reflecting on the evolution of the role of the enterprise in society in the experience of the 20th century it is possible to propose solutions to the decision-makers who are today designing the new European model of development and growth to meet the needs of the 21st century.

The role of the enterprise has been progressively defined within a discipline (Economics) that is a relatively young one and for this reason requires ongoing reflection to effectively guide present and future processes.

The origins of Economics can be traced back to the 18th century, when the economic systems, predominantly agrarian and commercial, underwent profound changes driven by the scientific and technical advancements of the era, that led to the first industrial revolution. This era not only introduced new, complex, and extensive production activities and processes but also marked the advent of spill-over effects between labour and capital, with significant social impacts. Consequently, a pressing need arose for a new discipline to govern the reorganization of resources and activities in accordance with the evolving scenario and respecting human dignity.

The binomial Economics and Values characterised liberal thought in 18th century European countries, standing at the centre of the reflection on the objectives of the emerging economic discipline. Economics, originating from Ethics, offers itself as a means to achieve objectives aligned with the value system of the society. The role of the enterprise is drawn in this contest and continually evolves over time.

The connection between Economics and liberalism is the feature of the Anglo-Saxon thought of the time, represented by Adam Smith, a moral philosophy teacher considered as the founding father of the liberal thought. According to him, the two fundamental actors in economic systems - the enterprise and the State - assume distinct yet complementary roles. The enterprise is tasked with ensuring full employment of productive factors for collective wealth, and the State is entrusted with regulating economic actions to foster private initiative and, consequently, economic, and social development (Smith, 1759, It. ed. 1995; Smith, 1776, It. ed. 2008)².

The advent of the second industrial revolution and mass production in the 20th century leads to a new era with increasingly complex challenges for the economic discipline. The early years of the 20th century are a period of intense ferment in the development of economic thought.

The 1929 crisis highlights the extent of market failures, attributed in part to large economic concentrations exacerbated by laissez-faire policies (liberism), and thus represents an opportunity to renew the Smithian liberal thought.

In the United States, the Rooseveltian model, considered the pioneer of modern neocapitalism, takes shape (Roosevelt, 1933). Roosevelt rethinks the State-market relationship assigning the (federal) State a central role in economic development. He thus launches a programme of investment policies and a new public institution (the federal authority or agency) to revitalise depressed regions, acting under conditions of economic balance and managerial autonomy. One

² In this period, also Italy takes part to the formulation of economic thought thanks to Muratori and Genovesi. The latter was assigned the first European chair in Economics (Chair of Commerce and Mechanics) in Naples in 1754. *Della pubblica felicità*, published by Muratori in 1749 by way of spiritual testament, constitutes a political treaty on good government, addressed to those (then the prince) called to this great responsibility. In Muratori the political aspect is closely connected to the social and thus to the economic one (Muratori, 1749, ed. 2016). According to Muratori government is necessary to deal with imbalances and disorders, anticipating what would later become the confrontation/conflict between liberalism and liberism. In the same direction is Genovesi, who explicitly draws a line of continuity between economics and philosophy. For Genovesi Economics is synonymous with good government of the *res publica* (Genovesi, 1768, ed. 2019).

example for all is the Tennessee Valley Authority (TVA), which, with its focus on good governance, succeeded in the market and revitalised the depressed Tennessee region (Bruzzi, 2011).

In this period Rosenstein-Rodan, Roosevelt's collaborator, proposes the theory of backward areas; he operates also in Europe through the IBRD (International Bank for Reconstruction and Development) to revive Europe's depressed areas after World War II. His is the "big push" theory generated by large-scale planned industrialisation (Rosenstein-Rodan, 1943).

In Europe too, the 1929 crisis creates the conditions for a renewal of liberal thinking.

In Germany in particular, the Social Market Economy begins to emerge. The 1930s are a very important period for the shaping of the German neoliberal thought. A decisive contribution comes from the Freiburg School which in these years, animated in hiding under the Nazi regime, lays the foundations of ordoliberalism (Eucken, 1951; Eucken, 1952; Vanberg, 2011; Felice, 2008). The term *ordo* highlights the need to define a new order, capable of guiding the economy of the time. It is a new economic order, based on a market economy, far from *laissez-faire* logic, in which the State assumes a strong regulatory role.

The ordoliberal constitutional order is guided by the respect for fundamental economic freedoms, e.g., freedom of trade, and freedom of private property, as well as the principles of civil responsibility and monetary and economic stability. Freedom and responsibility thus constitute the pillars of the German neo-liberal economic thinking. The 1940s are the historical period in which German neo-liberal thinking shapes the country's economic model, contributing to what would later be considered the German economic miracle.

It is also important to highlight the role played by the Catholic Church's social doctrine, through the formulation in 1931 of the principle of subsidiarity, particularly in its horizontal meaning. This is a meaning, still little understood today, that enhances the role of private actors, hence also of enterprises, in the socio-economic systems (Caselli, 2012).

After World War II, European neo-liberal thinking consists of a few main experiences; in France, Monnet founded the Commissariat du Plan: the public actor is placed at the centre of the economic and industrial policy. National public enterprise is then adopted as a mean to support the growth of the French national champions. France in these years also animates the birth of the first European industrial policy, with the creation of the ECSC and Euratom (Monnet, 1976). Germany, on the other hand, shapes the Social Market Economy within the federal State, enhancing the role of the State over the original proposal (Bruzzi, 2022).

Italy formulates its own approach to economic-industrial development, expression of a distinct cultural and political standpoint. During this period, some Italian Schools of Enterprise Economics and Management assume a pivotal role in guiding the process.

Methodology. The research methodology is defined according to the two objectives pursued.

The study of 20th-century American, European, and Italian models of development, now underway, is based on a systematic literature review of major contributions on the subject published in both major journals and monographs.

The study of the contribution of different authors and Schools of Enterprise Economics and Management will proceed methodologically in three steps.

The first step, currently in progress, involves a systematic literature review with two primary objectives: firstly, to systematise the Italian Enterprise Economics and Management literature concerning the construction of the enterprise theory at the basis of the Italian economic miracle of the 20th century; secondly, to describe the liberal thought developed at the international level to understand the context in which the Italian experience flourished, highlighting its uniqueness.

To better organize the contributions, the research proposes to categorize the literature around several main topics. These topics are delineated based on the research issues the Schools of Enterprise Economics and Management worked on, shaping, in the second half of the last century, independently but in synergy, the cultural and scientific mosaic of our discipline:

- The enterprise as a pillar of economic development - School of Venice
- The enterprise in major industrial, institutional, and international transformation processes - School of Pavia
- The systemic-vital approach - School of Rome
- The enterprise as an institute - School of Naples
- The enterprise theory - School of Turin
- The value theory - School of Milan Bocconi
- Internationalisation and industrial districts - School of Bologna
- Marketing and competitiveness - School of Pisa
- Corporate Social Responsibility, common good, and labour - School of Genoa
- Enterprise-territory relationship - School of Cagliari

In addition to monographs, the journal *Sinergie*, founded in Verona by Panati, plays a central role in the bibliographic collection. Around this journal, an interdisciplinary scientific community emerged, expressing its own voice, and contributing to the evolution of thought during that period.

The second step involves conducting in-depth interviews with the Masters and their pupils to understand the interrelations between various topics and the theory-practice relationship. The outcome of this phase will be the development of new and original interpretative models of the current Italian scenario.

In the third step, enterprises and institutions, the main stakeholders of the project, will be engaged to share and test the proposed solutions, using qualitative research techniques (e.g., focus groups and in-depth interviews).

Results. *With reference to the first objective, the outcome will be the reconstruction of the main features of the American and European socio-economic models emerging from the different national experiences, focusing on enterprises and the role they play in the pursuit of sustainable development and societal well-being.*

The analysis will then be able to nourish reflection on the common features of the different experiences that can provide a humus for the European model of development and growth now being defined.

Within the scope of the research, a prominent position will be assigned to the Italian experience (second objective) with the aim to delineate the characteristics of the Italian model from both theoretical and empirical perspectives. This study will be well rooted in the Italian reality of the 20th century, which remain highly relevant today. To this end the research will systematise the contributions from the different Italian Schools of Enterprise Economics and Management.

The result of the two goals will be a proposal for an original conceptual framework that can fertilize the new model of development and growth under construction in Europe today. The aim is not to define a new paradigm/theory but to envision an interpretative framework of reality from an evolutionary standpoint, as economy and enterprises are vital systems in constant transformation (Golinelli, 2000; Barile, 2006). Italian thought not only has the potential to catalyse a new cycle of economic development within Italy, as in the past, but also to contribute, in a subsidiary logic, to the international scientific debate seeking a conceptual framework aligned with the liberal tradition and able to address current needs.

The Italian model begins to take shape in the aftermath of World War II, with significant contributions from prominent figures who serves as civil servants, influencing the design of the economic and industrial framework of the time.

First, Saraceno plays a pivotal role in defining the Italian post-war development model and shaping the public-private relationship within the Italian neo-liberal experience.

The Italian experience stands out as a unique phenomenon in the landscape of the time. Noteworthy issues and business cases exemplify this distinction.

Firstly, public enterprise in Italy has acquired specific connotations since its origin. As Saraceno recalls, the 'IRI formula' is characterised from the outset by the exclusion of the public monopoly regime. IRI is a holding company that maintained stable shareholdings in private enterprises governed by private law (Saraceno, 1975).

This choice aligns with the Italian tradition, which since the 19th century favoured the public holding company managing State shareholdings ('ente di gestione'), as opposed to the prevailing model of the economic public institution (nationalized enterprise). These are two culturally distinct models: through the nationalized enterprise, the State operates in a monopolized sector. In the holding model, the State operates in multiple sectors according to a competitive logic to activate capital accumulation processes that incentivize private actors to enter the sector.

This is an extremely important point in the current process of building the new European model: what role should the public actor play in the European economy? On this front today, the Western model that has progressively reduced the role of the public actor (with some national exceptions such as France) is confronted with the Eastern model, where public enterprise still plays a strong role as an instrument of national industrial policies. The experience of the 20th century can fuel reflection on a point that for socioeconomic development and thus for sustainability remains crucial.

In the Italian capitalist model, born under the auspices of Einaudi's liberalism, State intervention serves as a solution to the weakness of private capital, with the final goal of promoting competition. A Keynesian intervention would have been ineffective given the acute shortage of private capital; public action to expand demand would not have resulted in an expansion of investment. Thus, the public actor has to assume the risk directly, but only at an early stage. The public enterprise thus becomes the instrument of an industrial policy where the general interest intersects with managerial requirements (Saraceno, 1959 and 1975).

IRI becomes an internationally studied model, providing Italy with an opportunity to stand out on the world stage. From this humus, a sensitivity to the development issues of the Mezzogiorno region emerges, with Saraceno playing a central role in initiating the so-called pre-industrialization policies inspired by Roosevelt's experience and brought to Europe by Rosenstein-Rodan. Rosenstein-Rodan decides that IBRD funding should finance industrial projects in Southern Italy through an ad hoc authority, separate from other industrial policy initiatives and inspired by the US authorities: the Cassa per il Mezzogiorno.

The investments made during the initial period (1950-60) are largely directed towards infrastructure to catalyse subsequent industrial development. Through the "big push" theory by Rosenstein-Rodan, private investment is intended to be driven by public investment, thereby transitioning the environment from agricultural to industrial.

In this context, Saraceno addresses the North-South divide, a longstanding Italian issue that remains unresolved. Saraceno views depression in the South and stagnation in the North as two sides of the same industrial problem, emphasizing the need for a comprehensive approach that integrates investment and social policies (Saraceno, 1952). Saraceno in this perspective is a forerunner of the sustainability issues at the core of scientific and institutional debate today.

While Saraceno's objectives for enterprise good government face challenges, failing to overcome serious obstacles, it is undeniable that the policies and instruments implemented after World War II yield significant results and lay the foundation for the Italian economic miracle. For example, Italy excels in various heavy industries, e.g., in petrochemicals and steel production. At the petrochemical level, despite entering the market late and from a disadvantaged position following World War II, Italy affirms itself on the European and international markets.

ENI is established in 1953 under Mattei's leadership as part of a reorganization of all public oil activities. In line with Italian tradition, ENI functions as a holding with four subsidiaries: AGIP for fuel distribution, AGIP Mineraria for mining activities, SNAM for gas distribution, and ANIC for refining and petrochemical production.

ENI's approach also exemplifies Italian specificity. Mattei seeks to challenge the dominance of large integrated oil corporations (International Oil Companies) by entering into agreements that empowered the owner countries of oil reserves. The "Mattei formula" involves these countries in extraction activities through joint ventures, with costs and profits shared among partners. ENI assumes the risks of the venture and pays no royalties, but, if successful, joint ventures are established, with the country sharing the costs already incurred by ENI. The first agreement Mattei negotiates with this formula is with Egypt, resulting in a joint venture with ENI holding 20 percent. In 1961, Mattei signs an agreement with the USSR for oil supply in exchange for the export of synthetic rubber, initiating economic relations amid the Cold War that would be further strengthened in subsequent years (Frusciante, 2012).

Mattei's approach marks a discontinuity from the internationally dominant US corporation model based on mere competition, boosting Italy to a prominent position on the world market as Europe's refiner (Mazzaferro, 2021).

Italy's current foreign energy policy towards neighbouring Africa and Middle Eastern countries still reflects Mattei's approach. This demonstrates the long-term strength of a strategic approach to business, diverging from a purely managerial perspective (Bruzzi, 2023).

Of course, the Italian experience is not solely characterised by the public holding company. Private enterprises also exemplify an original model. One cannot fail to mention Olivetti, an enterprise that distinguished itself from US multinationals not only in the competitive arena of the IT sector but also in its ethical approach. Olivetti prioritized the growth and well-being of its employees and their families, emphasizing community building through the enterprise, which transcended mere economic dimensions (Olivetti, 1951 and 1959). Olivetti's legacy remains a lesson to the world on the political and cultural dimensions of the enterprise, deeply rooted in the Italian tradition of the teachings of various Schools of Enterprise Economics and Management. According to this tradition, enterprises are institutions designed to create wealth, economically and socially, with a long-term orientation. They operate within relational contexts that are both humus of economic activity and a product of it. In this perspective, enterprise sustainability (good government) and social well-being are mutually reinforcing (Caselli, 1995 and 1997).

Within this network of relationships, small and medium-sized enterprises, agile and flexible and therefore able of occupying global niches and of coping economic challenges, can succeed. Industrial districts, where such enterprises mutually support each other, represent another Italian specificity that in the past proved to be effective in responding to international competition (Beccattini, 1987; Lorenzoni, 1990 and 1992).

Italian scholars have played a crucial role in highlighting at the international level the uniqueness of Italy's industrial concentrations. Italian districts have become symbols of an internationalisation process that strengthens entire territories, not just individual enterprises (Lorenzoni, 1997; Usai, 2004). This underscores the strategic and value-oriented nature of enterprises (Sciarelli, 2002).

Similarly, the study approach oriented by the European vision highlights that the European integration process is a political alternative to globalisation, regulating competition and thus reducing opportunities for exploitation of unregulated arenas and gaps. Placing the study of enterprise in the context of the process of European integration means recognising, in line with the liberal tradition, the importance of creating institutional frameworks where enterprises can grow and become drivers of development (Usai and Velo, 1995; Velo, 2004). The European context moreover can be humus of innovative entrepreneurial formulas: the European Union in strategic sectors has supported new types of enterprise, such as the European Joint Undertaking, which in different strategic sectors (energy, space, medical research, etc.) has taken, in line with the principle of subsidiarity, different forms to support the different needs pursued: public-private collaboration, industry-research collaboration, economic development, technological innovation (Velo, 2007).

With reference to the research output, given the breadth of the content, it may consist of multiple publications, including both scientific articles focused on specific issues and monographs that can offer the broadest vision and the best coordination between issues. In all cases, the publications will be well anchored in current reality and will have as their main driver to contribute to the construction of the new European model of development in which enterprises and society can prosper.

Research Limitations. *The limitations of this research are primarily attributed to the limited resources available. This project encompasses a broad cultural scope, necessitating the involvement of numerous academic souls rooted within the Enterprise Economics and Management scientific community. However, these limitations can be mitigated if the project acquires support from academics across various Schools, thus creating the intellectual critical mass essential for achieving the final objective.*

Managerial Implications. *The managerial implications of this research hold significant relevance both from the theoretical and from the practical point of view.*

The proposal for a new interpretative framework will be useful to the two targets of the research: policy-makers, who today are defining the new European model of development and growth, will be able to find in the research a systematic reflection that can help define solutions consistent with European liberal and neoliberal thinking, mitigating the influence of forces against order, development, and peace.

Enterprises will be able to build strategies and practices around a platform of values, models, and contents, able of empowering each stakeholder to forge its unique entrepreneurial path within a variable geometry logic. Small and

medium enterprises constituting the Italian industrial fabric will benefit from anchoring their choices to a scientific discussion on historical models and forward-looking proposals, enabling to fortify both their sustainability and competitiveness.

Originality of the Paper. *The European economy, lagging far behind as vulnerability factors continue to worsen, urgently needs practical solutions to the many ongoing crises. The situation calls for the Academy to play its part. As in the post-World War II period a part of the Academy contributed through thought and action to the construction of the model on which the Italian economic miracle flourished, today we are called upon to contribute to the governing of the transformation taking place. To this aim this research proposes to construct an original interpretative framework consistent with the Italian tradition of the discipline of Enterprise Economics and Management and the liberal thought.*

The strength of Nutriscore in improving sustainable eating habits and well-being: bad and good news

ORNELLA BONAFEDE¹ CARMELA D'AGOSTINO² ANDREA BAZZANI³ GIUSEPPE TURCHETTI⁴
LEOPOLDO TRIESTE⁵

Abstract

This study represents the initial assessment of Nutriscore's efficacy in shaping perceptions of food healthiness in consumers. Nutritional labels are becoming increasingly common for effectively conveying messages to consumers and are adopted by institutions to develop policy strategies aimed improving collective awareness of healthy dietary habits. The efficacy of a nutrlabel is defined as the capability of Nutriscore to guide judgments and perceptions of food healthiness, overcoming barriers generated by personal characteristics and education.

To assess the evocative strength of Nutriscore versus the associated characteristics of the product, we conducted a laboratory experiment wherein we manipulated visual stimuli by misrepresenting Nutriscore labels on both healthy and unhealthy foods.

Our findings revealed a significant propensity for errors in assessing product healthiness, with half of the sample committing more than four errors out of six tests. Interestingly, these errors did not correlate with the type of food, consumers' education level, or food literacy. However, gender was a significant factor, with males making more errors than females (p-value: 0.021).

Consequently, it appears that consumers are more influenced by Nutriscore than by inherent product characteristics, underscoring the label's strong comprehensibility. However, this influence can have negative implications as Nutriscore's algorithm is built on criteria that generate paradoxical associations between scores and dietary guidelines. For instance, Nutriscore standardizes nutrient quantities based on 100g portions rather than considering consumption frequency. Future food labels should reflect healthiness relative to consumption frequency, employing simple yet effective designs akin to Nutriscore.

Methodologically, this paper proposes a straightforward approach for managing and evaluating the efficacy of both current and prospective food labeling systems.

Keywords: nutrition label; food choice; healthiness perception; public eating habits

Abbreviations

FL: food literacy

HP: Healthiness Perception

MD: Mediterranean Diet

NS: Nutriscore

Framing of the research. *Institutions are addressing the promotion of a healthy lifestyle to mitigate modifiable risk factors associated with non-communicable diseases, which account for 80% of the disease burden in Europe, totaling €1,179 billion in 2021 (Eurostat, n.d.). Encouraging well-being in Europe could potentially lead to a reduction of up to 70%, significantly alleviating social burdens, reallocating funds to other welfare initiatives, and bolstering economic productivity and growth through a healthier workforce (Public Health - European Commission, n.d.).*

Dietary patterns play a crucial role in influencing lifestyle and well-being, prompting institutions to develop policy strategies aimed at enhancing collective awareness among citizens. Although citizens' healthy eating habits are influenced

by various internal and external factors (Marcelino et al., 2001; Remick, 2009), institutions can enhance public knowledge by adopting policies that convey messages to promote healthy food choices.

Since 2011, the European Commission has mandated the inclusion of nutritional tables on product packaging to display quantitative product characteristics, such as the amount of carbohydrates, protein, fat, saturated fat, and salt. However, subsequent studies have shown that this instrument may not be accessible to everyone, particularly those without expertise in the field (Storcksdieck genannt Bonsmann, 2020). Consequently, front-of-pack nutritional labels have gained importance, with many countries adopting logos on a voluntary basis. In Europe, 63% of member states have implemented various logos, with Nutriscore being commonly adopted by Belgium, France, Germany, Spain, Luxembourg, and the Netherlands (European Commission, 2020).

Front-of-pack nutritional labels are categorized into three classes: "directive," "semi-directive," and "non-directive," each providing consumers with varying levels of interpretation regarding the healthiness of the product (Donini et al., 2023). Nutriscore, belonging to the directive category, utilizes a color-coded system accompanied by alphabetic letters from A (green) to E (red) to indicate the product's nutritional quality. Despite its graphical clarity, the algorithm used to generate Nutriscore scores has sparked controversy, as it may yield paradoxical scores compared to national guidelines based on frequency advice, potentially leading to consumer misinterpretation.

Despite the contentious nature of the scoring algorithm, the Nutriscore logo effectively communicates nutritional information in a clear and straightforward manner, making it accessible across different socio-economic statuses (Talati et al., 2019). This characteristic is crucial for disseminating nutritional information to the entire population.

Since the nutritional label is presented on the front of packaging, a lot of researchers have investigated how changing the position of nutritional label changes the visual attention of consumers (Dan J & Robert W, 2011). The same methodology has been adopted to compare which nutritional label was more effective in catching the consumer attention (Siegrist et al., 2015). Although from the literature we know that internal characteristics can also play a role in shaping dietary habits. For example, being female increases the probability of having higher food literacy and paying more attention to nutritional characteristics than men (Trieste et al., 2020). Also, the personal propensity to be more active at a certain time of the day (chronotype) can change eating habits; indeed, evening types appear more inclined to adopt an unhealthy diet (Teixeira et al., 2022).

Purpose of the Paper. This study aims to investigate the effectiveness of Nutriscore in shaping consumers' perceptions of food healthiness.

The relevance of this investigation stems from two main objectives: firstly, the widespread adoption of Nutriscore may influence the food perceptions of many citizens, especially if it were to be adopted by additional states. Secondly, the controversial algorithm used to calculate Nutriscore often produces scores misaligned with Mediterranean dietary guidelines, which have proven to be a preventive measure against non-communicable diseases (Tsigalou, 2020).

We examine three dimensions to evaluate the efficacy of the Nutriscore logo: (i) visual attention, (ii) influence on perception or judgment of food healthiness, and (iii) independence from personal characteristics such as education level, food literacy, and other consumer traits.

To guide our study, we formulate the following research questions:

1. Can personal characteristics such as age, sex, BMI, chronotype, adherence to the Mediterranean diet, probability of developing eating disorders, and declarative approach to choosing the healthiness of logos influence visual attention?
2. Does visual attention to the logo affect error rates?
3. Are error rates influenced by personal characteristics?
4. Does the Nutriscore logo impact error rates?

To the best of our knowledge, this paper represents the first attempt to assess the efficacy of Nutriscore in influencing perceptions of food healthiness.

Methodology. In our study the effectiveness of a nutritional label has been measured using three different criteria:

1. Visual attention.
2. The ability to influence judgment or perception of the healthiness of the associated food.
3. Independence of 1-2 from educational level, food literacy and, in general, the personal characteristics of the consumer. Indeed, beyond the confines of nutrients tables, the added value of a nutritional label lies in its ability to be understood by both educated and non-skilled consumers.

To assess visual attention, we employed eye-tracking technology, a neuroscientific tool used to measure how often and for how long participants' gazes were drawn to the Nutriscore logo. The adoption of this neuroscientific tool was crucial to assess if the consumers were attracted differently based on their profiling characteristics and also to ensure they saw the Nutriscore logo on the product packaging we showed them. This methodology has been previously utilized to investigate the logo's impact on consumer attention (Gastón Ares, 2013; Laura Bix, 2015).

The eye tracker Tobii tracks the gaze of the eye on a visual stimulus. The tool is non-invasive, and the participant does not even notice it since the black bar of eye tracker is positioned at the bottom margin of the computer screen and it blends with the color of the computer.

The derived variables were the total number of fixations on the label and product, and the total duration of fixations on the Nutriscore and product. Since the fixation area is significantly smaller for the logo than for the product, we considered the average per-fixation duration of the logo and the product when comparing attention to the logo and the product, respectively.

Since one the potential strength of a nutritional label is its ability to influence the perception of product healthiness, we detected whether the principal driver of perception was the label or the characteristics of the product by modifying the nutritional labels to induce incorrect judgments. The strength of Nutriscore is represented by the overall percentage of mistakes.

We selected 8 food packaging items, considering 4 healthy and 4 non-healthy products (defined as “healthy” those foods with a recommended daily frequency and “unhealthy” those with a recommended frequency of 1-2 times per week, according to the Guidelines of the Mediterranean Diet (MD), see Willett, 1995). Once we obtained the correct Nutriscore scores (ranking from A to E) using the related algorithm, we modified them, shifting each score by two positions: from B to D, in the case of healthy products, and from D to B in the case of non-healthy foods. We did not select products that were originally scored as A, E, and C.

The third criterion for evaluating the strength of Nutriscore involves correlating the percentage of errors obtained with personal characteristics. A lower correlation indicates a stronger performance of the nutrition label.

Experimental design

The study comprises two parts.

In the first session, we profiled consumers who consented to participate in the study through an online survey. The survey lasted for 13 minutes and requested anthropometric variables and validated questionnaire essential for understanding if personal characteristics could be linked to attitude towards packaging (visual attention) and personal characteristics. The survey was articulated into:

A) a series of validated questionnaires aiming to assess:

- declarative or substantial food literacy (SFLQ), (Corinna Gréa Krause et al., 2018)
- risk of developing eating disorder (SCOFF), (Francesca Solmi et al., 2015), adopted to screen for eating disorders, as niche literature has investigated the link between eating disorders and the differing attitudes towards food labels (K. E. Giel et al., 2011).
- Short Morning Evening Questionnaire (RMEQ) (Vincenzo et al., 2006), since literature suggests that evening-chronotypes are more likely to prefer unhealthy dietary pattern (Teixeira et al., 2022).
- adherence to the Mediterranean Diet (MEDAS) (Schröder H et al., 2011)

B) a set of additional items: height and weight (used to calculate BMI), sex, age, education (), and weekly frequency of food shopping, knowledge of NS.

In the second session, we examined visual attention and quantified the influence of Nutriscore on food perception.

To study visual attention, we conducted an eye-tracking experiment displaying eight Nutriscore-labeled food items on a computer screen. These items comprised three healthy products scored as B and three unhealthy products scored as D. Recognizing that the definition of “healthy food” varies depends on dietary patterns (Plasek Brigitta et al., 2020), we categorized the items based on the frequency of Mediterranean diet definition. We manipulated the scores by changing B scores to D and D scores to B. To minimize the likelihood of subjects detecting the programmed errors, two images with the correct labels were provided.

After each presentation, participants rated the healthiness of the foods shown on a 1-5 Likert scale. At the end of the experiment, each participant provided feedback on whether the product or the label guided their evaluation better. The discrepancy between the healthiness assessed by participants and the real value attributed by the Mediterranean diet represented the error in perception. Manipulating the logo was essential to verify the logo’s strength in shaping food perception. A higher percentage of error indicated greater trust that consumers had in the Nutriscore logo.

Results. Data analysis was conducted using R, version 4.2.2.

The independency of gaze metrics and the percentage of errors from personal profiling was assessed by comparing the medians of the total number of fixations and total fixation duration associated with Nutriscore and the product across different groups stratified by the profiling variables that defined the study population.

Independency of error percentage in the different groups was determined through a χ^2 test.

A p.value >0.05 for the Kruskal-Wallis tests and the χ^2 test, respectively, indicates that gaze metrics and the percentage of errors do not depend on consumer’s skills and education.

We collected a sample of 57 subjects with a mean age of 26.08 (SD= +7.65) with a balanced representation of 54% female and 46% male.

From the first session of the study, we had the opportunity to profile our sample, as summarized in Tabel 1 and Table 2.

Tab. 1: discrete variable of personal profiling

	Number (%)
Sex	
• Woman	31 (54%)
• Man	26 (46%)
Education	
• High school	22 (38,6%)
• Degree	30 (52,6%)
• Post-degree	5 (8,8%)
Driver:	
• Personal knowledge	30 (52,6%)
• Nutriscore logo	27 (47,4%)
Prior knowledge of the Nutri-Score	
• Yes	18 (31,6%)
• Not	39 (68,4%)

Tab. 2: continue variable of personal profiling

	Mean (\pm SD)	Max.	Min.	Median
Age	26.2 (\pm 7.8)	62	19	24
MEDAS	7.5(\pm 2.05)	12	4	7
SCOFF	2.1 (\pm 1.4)	5	0	2
BMI	22.3(\pm 3.16)	33.6	17.36	22.1
rMEQ	14.5(\pm 2.97)	20	7	15
SFLQ	34.7(+ 6.43)	47.4	17.6	34

MEDAS: assesses the adherence to mediterranean diet. From 0 (lower score of adherences) to 14 (higher score of adherences)

SCOFF: measure the probability of being more likely to develop eating disorders. From 0 to 5.

BMI: set the range of normal weight and non-norm weight. From 18.5 to 24.9 is normal weight, under 18.5 is underweight, over 25 is overweight, over 30 is obesity.

rMEQ: set the range of chronotype: 4–10 evening-type; 11–18 intermediate-type; 19–25 morning-type

We investigated the relationship between individual differences and sample characteristics.

Interestingly, women were more likely to adhere to the Mediterranean diet (p -value=0.02). On one hand, this result should be interpreted as females being more conscientious about their diet, thus adhering more closely to Mediterranean concepts. On the other hand, it suggests that this conscientiousness can sometimes manifest as excessive concern, potentially laying the groundwork for eating disorders; indeed, women also exhibited a higher probability of developing eating disorders (p -value=0.0025), as extensively documented in the literature (Hsu, 1989).

Additionally, individuals with high adherence to the Mediterranean diet (highest level of MEDAS) reported judging products based on their own knowledge (p =0.005) and being familiar with the Nutriscore logo (p =0.034).

To address the research questions, we divided the results into three sections: firstly, the relationship between personal characteristics and visual attention; secondly, the relationship between personal characteristics and the rate of errors committed in evaluating the healthiness of products; and finally, the rate of errors and visual attention.

Overall, the product received a higher number of fixations and longer duration of fixation, as shown in Table 3.

Tab. 3, Description of the number/duration of fixation for product and for logo:

Gaze metrics	Logo	Product
Average number of total fixations	44.88 (\pm 21.95)	159.9 (\pm 35.34)
Average of total fixation duration (ms)	296.7 (\pm 175.11)	1785 (\pm 2365.24)
Average number of fixations on 8 stimuli	5.61 (\pm 2.74)	159.8772 (\pm 35.34527)
Average fixation duration on 8 stimuli	1657.064 (\pm 1086.077)	6106.154 (\pm 1915.872)

Attention and personal characteristics

We also assessed if personal characteristics (e.g., age, sex, education, Body Mass Index, etc.) could influence the duration of gaze spent on the Nutriscore logo or on the food product image, both displayed on the front of the packaging.

We found a statistically significant relationship between individuals who reported judging the product based on their own knowledge and those who did not. Specifically, individuals who judged the product based on their own knowledge looked at the product image several times more frequently (p -value: 0.04) and for longer durations (p -value: 0.009). Additionally, the data indicates that individuals with higher levels of education (undergraduate and postgraduate) spent more time (p -value= 0.02) looking at the logo compared to those with lower levels of education (high school).

Errors and attention

Comparing attention and errors, subjects who made numerous errors, as expected, had a lower total fixation count (p -value: 0.005) and shorter duration of fixation (p -value: 0.0278) on the food stimuli images than subjects who made fewer errors.

Attributed to incorrect labels, the frequency of judgment errors regarding the healthiness of products was significantly higher in males than in females (*p*-value of the Kruskal-Wallis test = 0.021). Subjects adhering to a Mediterranean diet (i.e., with a high MEDAS score) made fewer errors (*p*-value of *t*-test = 0.06). Individuals who claimed to make choices based on their own knowledge made fewer errors (*p*-value of Kruskal test = 0.000).

BMI (*p*-value = 0.994), propensity for developing eating disorders (*p*-value = 0.513), chronotype (*p*-value = 0.759), education (*p*-value = 0.540), and the level of acquired food literacy (*p*-value = 0.467) did not correlate with the number of errors. These data highlight the effectiveness of Nutriscore in influencing judgments about product healthiness, regardless of certain personal characteristics relevant in traditional nutritional labeling, such as food literacy and education. If the goal of Nutriscore is to mitigate personal differences and educational barriers, it has indeed achieved its objective.

Research limitations. The study's findings are indicative of a digital environment, such as online shopping. Our future objectives include exploring outcomes in a physical setting to compare consumer reactions. Regarding the sample demographics, the mean age of 26.2 suggests that the results are representative of a specific demographic within the population. We aim to enhance the sample to obtain results that encompass a broader population. The research is work-in-progress.

Managerial implications. Nutriscore appears to be highly intuitive and effectively conveys the perceived healthiness or unhealthiness of food. However, despite its apparent simplicity, the algorithm underlying Nutriscore can inadvertently create paradoxes that consumers may not readily discern. These misunderstandings have the potential to lead to unhealthy dietary choices, undermining the label's intended purpose and leaving the challenge of promoting nutritional awareness unresolved.

Based on the findings of the study, it is imperative to address the gaps inherent in the algorithm, considering various aspects. For instance, the algorithm should consider the food category to which a product belongs, aligning with dietary principles such as the Mediterranean diet. Otherwise, foods from vastly different categories may receive the same score, leading to confusion. For example, a vegetable pizza, zero-calorie Coca-Cola, and chips might all receive a B grade, despite their disparate nutritional profiles and consumption frequencies.

The present study also highlights the urgency to revise the algorithm behind the logo and lays the foundation for investigating how to implement the algorithm to create an updated version that avoids the production of paradoxical scores. The innovation of the algorithm should take in account that the final score of the product should align with the Mediterranean diet, as it is currently, the most studied dietary pattern and has been revealed to be the most successful in combating Non-Communicable Diseases. If the new algorithm of Nutriscore aligns with these indications, it would be a very effective logo.

Originality of the paper. To the best of our knowledge, this paper represents the first investigation into the strength of NutriScore, offering a general prospective by testing the effectiveness of nutriscore on stratified target groups.

Does organic food consumption impact subjective well-being? A mediation-moderation approach

CELSO AUGUSTO DE MATOS¹ MARLON DALMORO² MARCIA DUTRA DE BARCELLOS³

Abstract

Does eating organic food make people feel good? If so, under what circumstances? Previous research has suggested an association between happiness/pleasure and the consumption of organic food. Health concerns have been demonstrated as a moderator. However, there is still a need to understand better the boundary conditions for the effects of organic food consumption (OFC) and subjective well-being (SWB). More specifically, what variables can influence this process? For instance, which mediators and moderators can improve our understanding of the OFC-SWB relationship? This research aimed to propose and test a model that explains the OFC-SWB relationship, considering the mediation effect of emotional process (self-enhancement) and the potential moderation of food-related lifestyles (FRLS), health concerns, environmental concerns, and locavorism. The model is tested based on data from a survey of 581 organic food customers. Our findings suggested a significant mediating role of self-enhancement between OFC and SWB. Moreover, FRLS and locavorism were significant moderators for the path OFC-self enhancement. On the other hand, health concerns and environmental concerns were not significant moderators. Finally, the study also shows that consumers who prepare their meals have higher scores on the index of organic food consumption. The same occurs for older and more educated consumers. The research finishes with a theoretical discussion and practical implications.

Key words: organic-food; well-being; self-enhancement; locavorism; food-related lifestyles; health concern

Framing of the research. *Responsible production/consumption has been one of the sustainable development goals (SDG 12) proposed by the United Nations since its 2015 meeting (UN 2020). Indeed, mass production patterns are becoming unsustainable and creating severe environmental problems, e.g., climate change and global pollution, and hence there is a need to understand better the drivers of more sustainable choices (e.g., Betzler et al. 2022; D'Souza et al. 2022). Food consumption is a key issue in sustainable development goals due to its impact on individual and public health, natural resources, social cohesion, and the economy (Kerr et al. 2023; Schleiffer et al. 2022). Thus, to reduce the environmental impacts of food production and consumption requires developing more sustainable alternatives, such as organic food and the agroecology system (Jürkenbeck et al. 2023; Kerr et al. 2023).*

Sustainable food involves mainly healthy and environment-oriented alternatives in substitution of conventional and agrochemical-intensive agri-food options (Kerr et al. 2023). Organic food is one of these alternatives because it is free of pesticides, synthetic fertilizers, or products that can cause damage to health, in addition to using techniques and procedures that respect the environment and preserve the quality of the food (Kerr et al. 2023). Hence, organic food consumption deserves attention as one of the more prominent and global consolidated alternatives toward sustainable food consumption (Rizzo et al. 2020; D'Souza et al. 2022).

In this sense, following previous studies, organic food is considered a healthy and environmental-oriented food production mode (Reganold and Wachter 2016). However, previous studies about organic food consumption present mixed findings regarding how people express their health and environmental concerns in their choices (Apaolaza et al. 2018; Tandon et al. 2020). Indeed, considering that an individual's purchase and consumption signal his/her lifestyle to people in his reference group (Jung et al. 2020), it is common for consumers to choose products/services that promise greater care for the planet, especially when this choice appears in public (Semila and Panda 2019).

In addition, a few research has shown that organic food consumption is associated with individuals' happiness and well-being. For instance, Apaolaza et al. (2018) supported the influence of organic food consumption on subjective well-being (OFC-SWB link). They argued that such an effect could be influenced by both cognitive processes (e.g. healthy diet beliefs) and emotional mechanisms (e.g. label effect). Moreover, such effects were stronger for consumers who presented a higher health concern. The study suggested that the organic claim acts as a heuristic cue guiding consumers to believe that the product will increase their well-being. Indeed, recent study has called attention to pleasure mechanisms as predictors of organic food consumption (e.g., Cao, Zheng & Li, 2024). In a similar fashion, Nguyen et al. (2024) explored

¹ e-mail: celso.matos@tecnico.ulisboa.pt

² e-mail: marlon.dalmoro@ufrgs.br

³ e-mail: marcia.barcellos@ufrgs.br

the OFC-SWB link by examining the subjective well-being impact on pro-environmental consumption behaviors. However, the authors' conclusion describes the role of moderators (e.g., environmental concerns) in explaining the OFC-SWB relationship. In complement, mediators like consumers' expectations for quality attributes and sustainability can influence the relationship between organic food purchase decisions and the subjectively perceived benefits, as argued by Martini et al. (2024), based on a qualitative study of Italian consumers. In dialogue with these previous studies, we concentrate efforts on exploring the boundary conditions between purchase decisions and subjective perception by exploring the concerns, ideological-related lifestyles, and subjective motivations that operate these boundary conditions.

Purpose of the paper. Based on the previous discussion, the current study aims to (i) advance the investigation on the non-cognitive process that acts as a possible mediator between organic food consumption and the consumer's perceived well-being, and (2) test the moderating role of additional variables not considered in previous studies, namely food-related lifestyle (FRLS), locavorism, environmental and health concerns. A conceptual model was developed based on the literature review. The proposed model is presented in Figure 1.

Methodology. The research was composed of four stages. First, a literature search was carried out to identify studies that had measured the constructs of this research. Following the literature search, we filtered a set of empirical studies that supply consistent scales to measure each construct.

Second, we structured the questionnaire and the scale items for each construct of the proposed model, as described below:

Organic food consumption was measured by four questions that evaluated the individual's behavior regarding the purchase and consumption of organic foods, namely: a) How many times a month do you usually buy organic food? (median = 4); b) On average, how much money do you spend monthly on organic food? (median = US\$ 24); c) How long have you been thinking about organic food as an option? (median = 3.0 years); d) Which of these organic foods do you buy most often? (list with 17 options). A scale was created that first added the answers (min = 1; max = 17; median = 6) and then standardized with a z score.

The reported behavior of organic consumption was preferred, rather than the commonly used behavioral intentions, to minimize the common method bias (MacKenzie and Podsakoff 2012), using the same approach as Bravo et al (2013). Other studies have also adopted a similar approach, i.e., measuring the reported behavior construct (Azzurra et al. 2019; Nam 2020; Pestek et al. 2018; Liang 2014). Each item on this scale was converted to a z score to standardize the scale (Malhotra and Birks 2007).

Well-being was measured at the beginning of the questionnaire with 7 questions, on a scale varying from 1 = no part of the time, to 7 = all the time. The anchor was "In the last 30 days, to what extent did you feel..." and the items were Happy, In a good mood, Extremely happy, Calm, Pacific, Satisfied. The seventh item was, "In general, how do you rate your satisfaction with your life? (Terrible 1 2 3 4 5 6 7 8 9 10 Excellent). This scale was adapted from Howell et al. (2013).

Self-enhancement was measured by 4 items adapted from Gong (2018), on a Likert scale (1 = completely disagree; 7 = completely agree), with the following statements: I feel excited when I buy organic products, My self-esteem improves when I buy organic food, I have more respect for myself when I buy organic products, Buying organic food makes me feel good in front of other people.

Food-related lifestyle (FRLS) was measured by 4 items adapted from the scale of Wycherley (2008). We focused on the dimension of "ways of shopping" because it provides content for the cognitive evaluations/beliefs regarding food consumption. A seven-point Likert scale was used with 1 = completely disagree and 7 = completely agree. The following items were used: a) For me, information about food is very important. I need to know what the food contains; b) I usually read and compare the labels of different brands before deciding on a purchase; c) Shopping for food is fun for me (reverse); d) I usually make a shopping list before going to buy food.

Locavorism was measured by 3 items adapted from Reich, Beck, and Price (2018), with the following statements: a) Food produced locally (e.g. your city) is more nutritious than those that arrive from other regions or outside the country; b) I don't trust foods that were produced by large companies (e.g. multinationals); c) I like to support local farmers whenever possible. Responses were given on a seven-point Likert scale.

Health concern was measured by 3 questions, using a seven-point Likert scale, based on Guilabert and Wood (2012) with the items: a) I worry about health risks and try to take steps to avoid them; b) I try to avoid health problems before I experience any symptoms; c) I care about the nutritional value of the food.

Finally, environmental concern was measured by 3 questions, based on a seven-point Likert scale, from Chen (2007), with the items: It is important to me that the food I eat daily has been ... a) prepared in a way that does not harm the environment; b) ... produced in a way that did not upset the balance of nature; c) ... packaged in an environmentally friendly manner.

The final section of the questionnaire included demographic data such as age, gender, income, and education level.

We pre-test the questionnaire with ten organic food consumers before starting the data collection. Finally, it was applied to a sample of food buyers at an organic farmers market in Porto Alegre, the capital city of the southern state of Rio Grande do Sul in Brazil. The south of Brazil is a relevant context to study organic food consumption because this region has a higher level of organic food consumption than other Brazilian areas (Organis, 2022). This market is a premier marketplace for organic food, where both farmers and consumers are connected with agroecological principles involving environmental concerns (Dalmoro et al. 2020). Data were collected from a non-probabilistic sample of consumers who agreed to answer the questionnaire while visiting the farmer's market. In collecting data in a real scenario of organic food shopping, we could access real organic consumers, fostering external validity. The questionnaire was

available on tablets, and participants self-completed the questionnaires after instructions from the researchers. The survey obtained a sample of 581 participants.

In the third stage, data preparation was carried out. After checking for missing and outliers, 2 cases were discarded. Therefore, a total of 579 participants were analyzed in the following steps. Then the reliability of the scales was analyzed. Overall, all scales achieved Cronbach's alphas greater than 0.60, thus supporting the reliability criteria (Malhotra and Birks 2007). Only in the organic food consumption factor, the Cronbach's alpha was relatively lower (0.63), which is consistent with the argument that formative scales do not follow the logic of inter-item correlations and, hence, Cronbach's alpha is not a requirement (Jarvis et al. 2003).

Finally, in the fourth step, our study presents the descriptive statistics and sample profile, correlation analysis, and the test of the proposed model. Data were analyzed using SPSS and the Partial Least Square (PLS) technique for structural equation modelling.

Results. The sample was represented by 60% female; 38% between 21 and 30 years old, followed by the group between 31 and 40 years old (21%). There was similar participation of single individuals (46%) or in a stable relationship (44%). A total of 54% had completed college or postgraduate education. A total of 42% of the sample has a personal income of up to US\$ 400 per month, and 77% had an income of up to US\$ 1,000 per month.

The dependent variable of this study, the consumption of organic food showed that on average, the participants purchased four times a month. Regarding the monthly expenditure on organic foods, a median of 24 dollars was observed, indicating that half of the sample spends at least 24 dollars per month on organic foods. Overall, the participants have a good experience purchasing organic food, since 50% or more started thinking about organic food at least three years ago. The average for this item was 5.8 years. On average, six items out of the seventeen presented, were purchased more frequently, namely: bananas (71%), tomatoes (62%), lettuce (60%), carrots (54%), eggs (50%), broccoli (46%), and apples (40%).

An analysis of the correlations indicated that the organic-food consumption score presented a significant correlation with all the remaining variables, with stronger values for environmental concern (.36) and health concern (.32), with all correlations significant at the 0.01 level (see Table 1). The same was true for well-being, which presented higher correlations with health concern (.23) and FRLS (.23). Locavorism presented relatively higher correlations with self-enhancement (.52) and environmental concern (.50).

Tab. 1: Correlations

	1	2	3	4	5	6	7
1. Wellbeing	1						
2. Organic food consumption	.12**	1					
3. Self enhancement	.14**	.23**	1				
4. FRLS-ways of shopping	.23**	.14**	.37**	1			
5. Locavorism	.17**	.28**	.52**	.26**	1		
6. Health concern	.23**	.32**	.33**	.29**	.32**	1	
7. Environmental concern	.17**	.36**	.46**	.29**	.50**	.36**	1

Note - ** correlation is significant at the 0.01 level; FRLS = food-related lifestyles

Based on these findings, the following analysis was to test the structural relationships between the variables, as predicted by the proposed model (see Figure 1). From the main findings of the model test, we can highlight four issues.

First, self-enhancement was a significant full mediator between organic food consumption and well-being, especially because the direct effect was not significant.

Fig. 1: Theoretical Framework and Structural Model

Second, FRLS presented a significant moderating effect, with a negative coefficient suggesting an attenuation effect, i.e., that the higher the evaluations in FRLS (meaning greater cognitive aspects, such as product information) the lower the influence of the organic food consumption in the self-enhancement, which is in agreement with expectations. In other words, for those customers of organic food who follow a more cognitive route (give high importance to product information), there will be a smaller influence of organic food consumption on self-enhancement, which is in agreement with the “label effect” proposed by Apaolaza et al. (2018).

Third, locavorism was also a significant moderator in the link between organic food consumption and self-enhancement. The positive coefficient suggests that locavorism strengthens the influence of organic food consumption on self-enhancement, i.e. the higher the locavorism, the stronger the link between OFC and self-enhancement.

Finally, health concerns and environmental concerns, on the other hand, did not present significant moderating effects.

Research limitations. Finally, the current research also has some limitations. For example, only farmers’ market shoppers were surveyed. Future studies may also include consumers in different purchasing contexts, such as supermarkets. For that, researchers can explore specific mediators like the role of conspicuous consumption, given that organic food is usually positioned as a premium product. In addition, the observational approach (survey) could be complemented with additional studies based on an explanatory strategy (experiment) by manipulating the moderators/mediators of the proposed model, as well as different scenarios for organic food purchases.

Managerial implications. Considering the implications for practice, there are two main aspects here that could be highlighted. First, the promotion of organic food could work to increase the consumer knowledge about the origin of the food, since higher importance given to the food produced locally (locavorism) is associated with higher organic food consumption. Second, the promotion of organic food could also use the peripheral route of advertising (Petty & Cacioppo, 2012), making use of positive emotions, for instance, and calling attention to the fact that organic food is not only healthy but makes you feel better.

Originality of the paper. Previous studies have demonstrated the influence of organic food consumption on consumers’ well-being (OFC-SWB). The current research addresses this issue and advances the discussion in two different ways. First, the model tested in this study examines moderators (i.e. food-related lifestyle and locavorism) that have not been analyzed in previous research about the OFC-SWB relationship. Second, the model also contributes to the extant literature by investigating the non-cognitive process (e.g. label effect) that acts as a mediator between organic food consumption and the consumer’s perceived well-being and thus supports the role of self-enhancement as a mediator in the OFC-SWB link.

As a final remark, our study details the ‘circumstances’ that explain the association between happiness and pleasure (Apaolaza et al. (2018) related to organic food consumption (Nguyen et al. 2024). In particular, the boundary conditions between OFC-SWB are not supported by itself, but improved by a set of mediators and moderators that influence the relationship. In the case of organic food consumption, ideological-related lifestyles (FRLS and locavorism) and subjective motivations (self-enhancement) have a higher impact on this boundary condition than individual concerns.

An improved framework for social sustainability: a bottom-up approach to boost social innovation and sustain employability

GIUSY SICA¹ ALESSANDRA MICOZZI² MARIA ANTONELLA FERRI³ MARIA PALAZZO⁴

Abstract

This short paper presents a framework to social sustainability that sees bottom-up activities and projects as a necessary starting point to reach social innovation. The contribution is structured in three parts. In the first one, the concept of sustainability is presented, based on its three main pillars, social, economic and environmental facets. The evolution of the relation between these three aspects is also discussed. The second part presents the first theoretical framework based on this definition and then suggests a modification to include the topic of co-creation and participation of the community, which has been until now almost always considered only as the mere recipient of social innovation actions. A practical example is then given, in the third part, to demonstrate that when the community is actively involved in every step of the process, social sustainability actions lead to social innovation. The objectives, methodologies and strategies of this approach are briefly described, as part of a larger funded research project, the WELLTS project (Work Employment Labor Logic Talent Scope), which aims to analyse the main changes that technology is creating in terms of workplace and social sustainability.

Key words: social sustainability; well-being; social innovation; open innovation; bottom-up approach; people-led; participation

Framing of the research. *The concept and definition of the term sustainability has increasingly become a global challenge (Heilman et al., 2021). In September 2015, 193 countries gathered to define and adopt the 17 Sustainable Development Goals (SDGs) of the 2030 Agenda for Sustainable Development. This led to the construction of European policy guidelines that consider the SDGs and recognize the fundamental role and benefits that innovation and creativity offer for economic and social growth (UNDP, 2015). The 2030 Agenda for Sustainable Development is based on the five P-keywords: People, Planet, Prosperity, Peace, and Partnership (Fourati-Jamoussi et al., 2021).*

Historically, the concept of sustainable development was first defined in the 1987 Brundtland Report as the development that meets the needs of present generations without compromising the ability of future generations to reach their own (Brundtland, 1987). Three are the fundamental pillars of sustainable development: environmental sustainability, economic sustainability, and social sustainability (Purvis et al., 2021; Amaral et al., 2023). Social sustainability, in particular, intersects the dimensions of well-being, social equity, access to social and health services and education, fair income distribution, good working conditions, equality of rights, social cohesion and inclusion, accountability and participation in policy making (Ly et al., 2023).

Over the years, the relative importance attributed to the three pillars of sustainable development has, however, changed (Colantonio, 2009; Yolles, 2018) as shown in Figure 1.

Fig. 1: Time evolution of the three pillars of the social sustainability

Source: Colantonio, 2009.

Before 2010, when a balance was achieved, the importance of the social innovation was always less than of the other two. According to Colantonio (2009), this phenomenon can be explained both by the difficulty of applying and understanding the characteristics of social sustainability, and because it is always marginalized by a society historically rooted in specific forms of environmentalism based on global capitalism models (Colantonio, 2009; Boström, 2012; Bottero et al., 2019).

Besides, there is still a lack of a clear and broadly accepted definition of the concept of “social sustainability”, despite the frequent use of this term in academic literature and political debates (Licht et al., 2021; Corsini et al., 2021). For example, Vallance et al. (2011) argue that the concept of social sustainability is in chaos, and this is seriously undermining its importance and usefulness. In contrast, Boström (2012) argues that the vagueness and flexibility of the interpretation of the concept cannot be completely overcome, but it is precisely this characteristic that has facilitated communication between stakeholders with a common interest, making it the conceptual tool that brings together various actors. Shirazi and Keivani (2019) argue that social sustainability acts as an empty signifier - it performs a task of organization within social discourse, but it lacks a definitive content. Lee and Jung (2019) add that following the evolution of the scope and interests of people and society may be more important to the discussion and actions than determining how to define social sustainability (Eizenberg et al., 2017).

The main challenge is that it is unclear how social sustainability relates to the other two pillars of sustainable development or to other social development issues (Martynov, 2020). The lack of a defined conceptual framework has led to a large increase in academic articles and studies since the late 1990s (Giddings et al., 2002; Litting et al., 2005; Hervani et al., 2017; Baranauskas et al., 2022). Furthermore, many works have highlighted that the division of sustainability into three dimensions (economics, environmental and social) is a limited and insufficient response to global problems. Different scholars have thus focussed on four/five dimensions in this field (Seghezze, 2009; Iordache, 2018, Grindheim et al., 2020; Najjar, 2022). Other papers have suggested a purely social vision, where environments and economies are transformed and considered only on the basis of the needs and desires of the community (Deigh et al., 2026; Alaimo et al., 2020).

Despite the proliferation of both theoretical and empirical works on social sustainability and its connection to the other pillars of sustainable development, it is only in 2016, with the work of Boyer et al. (2016, hereafter B16), that a clear theoretical foundation and a general framework on social sustainability are outlined. The work starts from recognising the ambiguity that surrounds social sustainability, compared to the other pillars of sustainability. Therefore, the main objective of B16 is to contextualise social sustainability within the general framework of sustainable development, and, above all, to start an interdisciplinary conversation on the major global problems of the 21st century (climate change, energy transition, etc.). Actually, the paper criticizes the three-pillars’ (economic, environmental, social) model of sustainability, considering it too simplistic and potentially misleading. The authors argue that, even today, this model often relegates social sustainability to a secondary element compared to the economy and the environment, neglecting its complexity and interconnection with the other pillars. B16 recommends instead an “integrated approach” that considers social sustainability as a central concept and intrinsically connected to the other aspects of sustainability, and therefore leads to the development of holistic solutions that simultaneously consider social and economic needs, justice, environment and human capabilities. This approach is based on the idea that in order to respond adequately to the presence of multiple realities, multiple social approaches were needed.

In summary, in order to respond adequately to the presence of multiple realities, multiple social approaches are needed. Starting from this assumption, B16 constructs five different typologies of applications of the social dimension in real contexts, reconsidering the role of social sustainability, its degree of integration and its relation to the environmental and economic pillars. For each typology, the paper outlines the main aspects (such as the objectives which need to be achieved) and the procedural aspects (how to achieve them) of sustainable development.

The five different roles for social sustainability in the broader picture of sustainability in general, presented by B16, are listed below:

1) Social sustainability is seen as an autonomous pillar separate from the dimensions of environmental and economic sustainability;

2) Social sustainability is perceived as a constraint for the economic and environmental pillars: sustainable development in this case is considered a process of reconciliation between the conflicting priorities of social equity, economic development and environmental protection;

3) Social sustainability is considered as the foundation for the other pillars, because it constitutes the stock of social capital necessary for economic and environmental development, allowing to compensate for its criticalities and shortcomings;

4) Social sustainability is seen as a stimulus for economic and environmental progress and as a causal mechanism for environmental and economic change because it is capable of promoting alternative ways of thinking, interacting or governing;

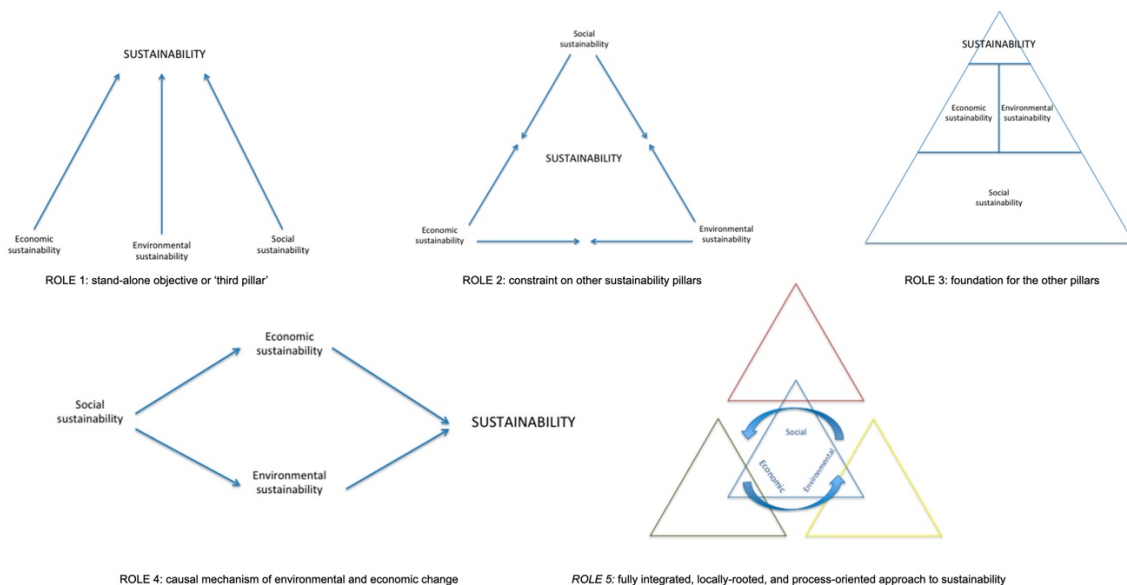

5) Social sustainability is perceived as fully integrated, locally-rooted, and process-oriented approach to sustainability for the development of communities and territories.

The paper states that there is the need to promote these five approaches to social sustainability in order to open a dialogue that can help researchers, professionals, and policymakers to define and apply the concept in a clearer and complete way.

Initiating an inter-disciplinary discussion which could lead to a definition of the social sustainability, is the main aim of this paper which, starting from the analysis in B16, proposes a modified version of its last approach (social sustainability as a process of integrated development of communities and territories) that better reflects on how to achieve social development with bottom-up social innovation practices.

A schematic view of the 5 approaches is shown in Figure 2, which is a summary of the 5 different figures in B16.

Fig. 2: The five different roles that social sustainability can have according to B16

Source: Boyer, Peterson, Arora, Caldwell, 2016.

Purpose of the paper. Although several studies have focussed on social sustainability and innovation (Souto, 2021), the relationship between the innovation and sustainability processes is neither obvious nor simple to be explored. To face the upcoming challenges towards a sustainable future and local development, policymakers and researchers are increasingly attributing a key role to people and their well-being (Kalkanci et al., 2018). However, the community is still too often considered only as the recipient of sustainable interventions and actions. The bottom-up approach to social innovation, i.e. that born directly from the citizens themselves, instead represents a model able to obtain effective results in terms of social and cultural progress, as well as economic and environmental insights (Puerari et al., 2018).

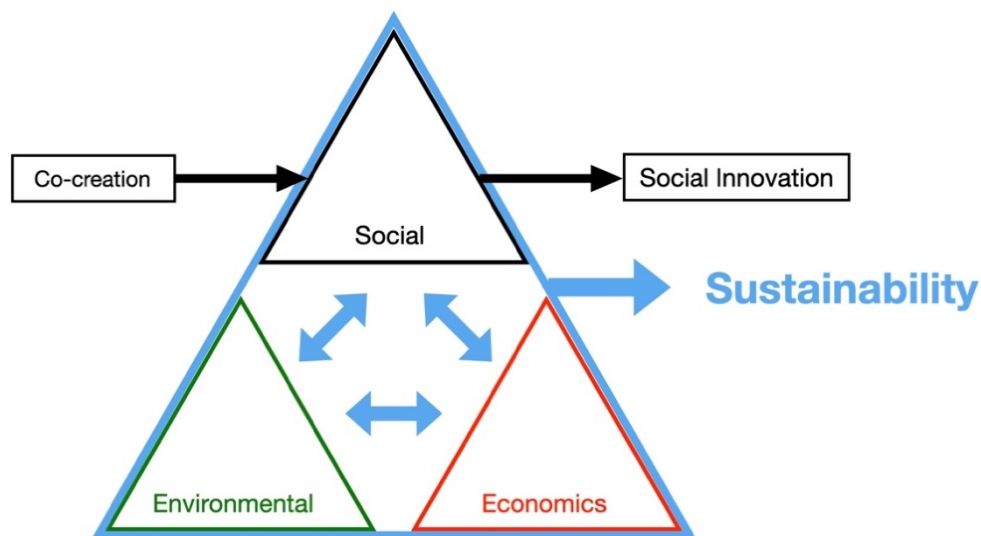

In light of these considerations, this paper proposes a modification of the 5th theoretical framework presented by B16, in which the social sustainability is a fully integrated, locally-rooted, and process-oriented approach to sustainability. The new framework introduced here, adds the fundamental concept of co-creation as the power behind each successful social sustainability action which automatically leads to social innovation (Grosse et al., 2020). The importance of the participation's aspect has been affirmed by the European Commission, according to this concept, the local human capital should take place in every single step of the sustainable development planning process.

In line with B16, the paper highlights that for each of the three pillars there are different agents with unique perspectives that must negotiate with each other. One of these agents is indeed the community, that should participate in all the phases of the planning, creation and realization of social innovation and territorial regeneration projects. Only in

this way, social, economic, and environmental priorities can aim to affect the experience of individuals. The framework is schematically shown in Figure 3.

Within the new framework, this conceptual study intends to investigate, starting from a specific case study's analysis, how fundamental for sustainability and social innovation is that the community plays an active role in the co-creation, planning and implementation of such interventions. This people-led approach is based on the collaboration of different social actors and stakeholders with different priorities and interests, but with the common goal of attaining sustainable development. The primary starting point is that the community activates itself "from below" with actions and practices of social innovation from which it will itself benefit, and which will automatically and naturally lead to social sustainability and sustainable innovation.

Fig. 3: A modification to the 5th framework by B16.

Source: Authors' elaboration based on B16. (The inter-connection of the three different pillars, represented by three triangles (environmental in green, economics in red and social in black) is the most effective way to reach sustainability (big light blue triangle). The black arrows entering and exiting the triangle of social sustainability represent causal mechanism and implication, respectively).

Methodology. The paper shows a conceptual study, setting the basis for an interdisciplinary discussion on the role and definition of social sustainability in the broader context of sustainability and social innovation. While empirical studies focus on collecting primary data from the real world, this research is based on a first intentional integration of previous theoretical results. Hence, a conceptual research design was adopted, in line with the scheme offered by Jaakkola (2020). As suggested before, a conceptual approach allows the creation of a bridge between different theoretical frameworks in an innovative way, thus broadening our understanding of a particular problem and triggering discussion and further research. However, since the "integrated approach" proposed by B16, assumes that the social approach is strictly linked to and dependent on the reality being analysed, in this study the discussion is also contextualized to the case of *Officina Keller*. This is an urban regeneration project carried out by the homonymous cultural and creative industry that has been operating in Naples since 2011 (*Officina Keller Napoli, OKN, 2011*). This project represents an important example of how people-led social innovation practices can be an important and concrete starting point to boost economic, social, and environmental development processes with a completely bottom-up approach.

Results. The historic centre of Naples is part of the World Heritage List. The strategy of the Municipality of Naples, with the Great UNESCO Project, has proposed, since 2007, a program of urban regeneration characterized by a strong integration of urban policies with those for social inclusion, social well-being and legality and security. The Great UNESCO project is divided into several blocks: some of them aimed at realising structural interventions and regeneration of the historic centre, other focusing on mitigating social discomfort, security problems, and improving the economic and social conditions of the inhabitants (Great UNESCO Project, 2007). This program, therefore, fits perfectly into the framework described by B16, which sees social sustainability as a process of integrated development of communities and territory. However, although representing a good step forward, the project has not achieved the desired results as the social and economic condition of the area is still problematic. The main reason for the 'partial' failure of this program, apparently excellent, is due to the fact that the regeneration actions were based on a top-down approach, i.e. planned, decided and carried out by the Municipality, without any confrontation with the inhabitants of Naples, that had no direct and only weak involvement in the decision-making and creative process.

OKN, on the other hand, has undertaken an opposite approach, realizing regeneration and innovation actions with a strong bottom-up connotation (Sica, 2022). The *Officina Keller* project starts from a territorial requalification, set and carried out by members of the local community: that of the recovery of the cloister of Santa Caterina a Formiello and the

area of the former wool mill (*Lanificio*) at *Porta Capuana* (Arcidiacono, 2017). Starting from the artistic and cultural vocation, OKN built a creative, artistic, and cultural hub, which is today a real workshop of ideas in which it is possible to share knowledge and promote the training and participation of numerous professional figures active in the sector of culture, training and economy. Specifically, the *Officina Keller* project has restored 3000 square meters of one of the most important examples of the Neapolitan Renaissance, which used to be wholesale shopping center in the second half of the century and then became a neglected place. At the same time, OKN has contributed to the creation of a high-level training school for craftsmanship and the realization of 11 residences for artists in-loco. In doing so, *Officina Keller* is currently the only regeneration project that has returned the regenerated space to the community, thus favouring the spread of an 'active' network within the *Lanificio* area. In addition to involving artisans scattered throughout the territory, also recovering a 'doing' capacity typical of the quality of *Made in Italy*, OKN, thanks also to the partnership with the social cooperative '*Dedalus*' and '*Officine Gomitoli*', has proposed, and still proposes, a series of active internships and school-workshops for young people from risky social groups (Sica, 2022). The project is thus able to intercept two increasingly disruptive problems, that of premature training/school dropout and the lack of integration into the world of employment. The idea is that for each job order a craftsman 'adopts' one or more individual to support them and involve them in his/her work. In this way, the objectives of reconversion and urban regeneration pursued by OKN are achieved not only through the revaluation of craftsmanship, but also and above all, through the creation of a new highly specialized workforce.

In conclusion, we believe that the vision of OKN is a multi-level one, both in terms of planning and policy, which determines high potential for sustainable development from social innovation and generating economic, territorial, environmental/digital innovation. The *Officina Keller* project demonstrates the potential of a bottom-up approach to urban regeneration and social innovation. The project has been successful in bringing together different stakeholders, including local residents, businesses, and government agencies, to work together and create a more sustainable community. The project has also been successful in generating economic, social, and environmental benefits. For example, the project has created jobs, improved the quality of life for local residents, and reduced environmental pollution. The *Officina Keller* project provides a valuable model for other communities that are seeking to create a sustainable future. The project demonstrates the importance of involving the local community in the planning and implementation of regeneration projects. It also shows the potential of social innovation to address complex social and environmental challenges.

The goals of OKN - urban regeneration, social innovation and social reconversion - make it a virtuous space that not only aligns with the objectives of the Agenda 2030 and more generally with the current and future European political strategies, but even surpasses them by maintaining a bottom-up approach involving all the actors - formal and informal - of its local territory. In the same way, the example of *Officina Keller* not only reflects the fifth framework introduced by B16, but overcomes it, introducing the concepts of co-creation and participation (Itten, et al., 2021; Anthony, 2023).

Hence, the paper concludes that participation is the most effective way to fully involve the local population and to create an endogenous management of resources that takes into account the needs of the community and a series of shared objectives that are able to simplify the participations' processes, also in line with other recent works (Bindi, 2019). Sustainable and participatory development therefore focuses on the community itself, its needs, potential and resources, and therefore differs from the traditional approach to economic development. This latter, and even more specifically from the place-based approach, in which social sustainability is a process of integrated development of communities and territory, instead, tend to attract resources from outside (Palazzo et al., 2022) In the framework proposed here, with the bottom-up approach, is the community that actively contributes to the development of the territory. The main objective in this new framework is to enable a reference community, with its system of stakeholders, to self-improve its quality of life, and at the same time regenerate its territory in a sustainable way, hence also making economy prosper. For this reason, the 5th theoretical framework of B16 can be modified, considering social innovation as the main driver of sustainable development.

Research limitations and future investigation. Social sustainability is a fundamental objective for the future of our societies. However, research in this field presents several challenges and limitations. As already stressed, the lack of a unique and shared definition of social sustainability represents a significant obstacle: the multiplicity of definitions and interpretations of the concept makes it difficult to compare studies and evaluate impacts. Furthermore, the lack of a clear conceptual framework limits the ability to develop robust theoretical models and identify effective measurement indicators. Social innovation can play a key role in improving this situation provided that adequate research and implementation strategies are developed (Kumar et al, 2022).

This study presents the typical limitations of a conceptual paper, built on a purely deductive basis, starting from the literature available on the subject, which is however in most of the cases contrasting. Moreover, and most importantly, most of the works in the literature have focused on aspects of sustainability that considered the social pillar (people) only as recipients of the other two levers of development (economic and social). Therefore, a future research agenda could:

1) Further investigate these issues following the perspective offered here, namely, to consider social innovation and methodologies related to participation and bottom-up approach as starting points and motors for sustainable development;

2) Better characterise and deepen the interaction between social sustainability and other aspects of sustainability, such as economic and environmental sustainability;

- 3) Study the impact of new technologies (such as artificial intelligence and blockchain) on social sustainability;
- 4) Since the case of *Officina Keller* is still in a preliminary phase, it would be advisable to carry out field research that could be able to offer more detailed and specific data to improve the understanding of the phenomenon under analysis;
- 5) Last but not least, future research could focus on a diversified choice of empirical case studies.

Managerial implications. The results presented in this study affirm that inhabitants' participation in the planning, creation and realization of social innovation processes is the engine to social sustainability. This requires a fundamental change to the managerial approach to social sustainability and innovation projects, as the community must be able to manage and get involved in the projects at every single step (Marradi et al., 2022). Indeed, this methodological approach assigns a very important role to all those stakeholders that usually do not take part in the decision-making process, even though they are directly interested by interventions and actions. This is initially done through the activation of workshops, focus groups, and questionnaires that can be used to understand the needs and desires of the local inhabitants in order to plan interventions and co-create projects that allow for better and more concrete project results (Strasser et al., 2020).

Not only the competent administrations, investors, and designers, are involved in the participatory process, but also representatives of civil society, associations, and social groups. The "top-down" managerial approach, that involve decisions taken exclusively by the administrations with pre-defined and well-set aims, is reversed and complicated (Micozzi et al., 2021) The actors, in this bottom-up cases, are multiple, everyone with their own skills, needs and priorities, which might differ from these of others. Compromise and communication therefore become of fundamental importance in the managerial and decision-making process (Palazzo et al., 2017). However, it is not possible to create a dialogue between different actors if they do not speak the same language, if a common background is lacking. Hence, a possible future path for research could be to identify new required skills and investigate on the possible way to training the administrative apparatus to provide adequate support to citizens and, consequently, push them to undertake co-creation actions (Moons et al., 2021).

Therefore, it is important to put a strong emphasis on new types of skills and knowledge in the co-creation and management of collaborative spaces, to strengthen bottom-up and social innovation approaches and foster improvements in the social, cultural, economic and environmental scenario (Palazzo et al., 2020). A concrete example is provided by the WELLTS project (Work Employment Labor Logic Talent Scope), which aims to analyse the main changes that digital technology is creating in terms of workplace and socio-cultural innovation. Indeed, the study carried out in the WELLTS project highlights how the development of employees and professional roles is closely linked to the evolution of technologies and at the same time to the diversification of demand needs in different territories.

Originality of the paper. The study contributes to broadening the debate on the implications of social sustainability by focusing on the fact that sustainable development should start from the bottom and through social innovation carried forward by people. The thesis puts forward in this work states that bottom-up social innovation, i.e. coming from the citizens themselves, probably represents the best way to activate local communities and the participation of citizens in the dynamics of development, with consequent positive results in terms of social and cultural, as well as economic, progress (Sica, 2021). Furthermore, the paper considers innovation as a particularly important factor in promoting sustainable development systems that favour the balance between economic growth, social development, and the protection of "public goods", such as biodiversity and other environmental resources (Qasim et al., 2021). In this way, social sustainable innovation represents an emerging paradigm that aims to address the major challenges of our time through innovative, technological, co-created and lasting solutions. It is a holistic approach that integrates different disciplines and sectors, from technology to economics, from sociology to environmentalism, with the aim of creating positive change in society (Cooper et al., 2018).

This paper proposes a revisitation of the 5th B16 model, reaching a definition of sustainable social innovation. Starting from considering the social sustainability like a development process integrated to community and territory, according to the theory of B16, this paper suggests to modify the framework, adding the engine of co-participation and co-creation of social innovation and territorial regeneration processes, as a *conditio-sine-qua-no* for the social pillar of sustainability, which then integrates with the economic and environmental ones. The co-creation methodology does not only aim to achieve a specific result from the social innovation perspective. It is also a tool that allows us to re-think the very way in which the relations of power between the various subjects involved are managed, and how innovation can practically be applied to concrete situations to achieve social sustainability (Trischler et al., 2023). The participation of the community throughout the entire innovation process, starting from the ideation and design phases, allows one to broaden the perspective of institutions and companies, by listening to a plurality of other instances and needs. This contributes to an integrated and concrete approach to sustainable development and innovation activities. Specifically, the work describes a practical example of a bottom-up project for the redevelopment of a neighbourhood in the historic centre of Naples, and in particular of a historic building of great artistic value, the *Lanificio Borbonico*. In addition to regenerating the territory, *Officina Keller* has caused a huge change in the existing community, letting the community itself decide how best to use the space available. With a completely bottom-up approach, the project has achieved concrete results of sustainable and social innovation, succeeding where top-down actions had dramatically failed.

Knowledge, self-perception and eco-sustainable behaviours. Inspiring actions in green learning

ADRIANA APUZZO¹ RITA KLAPPER² MARIALUISA SAVIANO³ MARIO TESTA⁴

Abstract

The study aims to examine the level of knowledge of sustainability understood in its triple dimension, economic, environmental and social, as well as investigate the gap between declared values and actual actions in the sustainable behaviour of students. This is addressed through an investigation into the individual perception of environmental responsibility and the actual adoption of sustainable behaviours, in order to evaluate to what extent the students, participating in a series of seminars on sustainability, internalize and translate the principles learned into concrete actions.

In line with thought of Hadjichambi and Paraskeva-Hadjichambis (2020) on the importance of sustainability education, the study focuses on the implementation of a training approach that emphasizes active and contextualized learning. The proposed series of seminars incorporates elements of investigation, planning, action, evaluation and reflection, with the aim of informing and making students more aware.

The survey method involves administering a questionnaire to a sample of students before, during and after the series of seminars on CSR and individual environmental responsibility. In future, it is planned to conduct a survey in Italy and other European countries in order to carry out a cross-cultural comparison.

Key words: education; sustainability; students; knowledge; perception; behaviour

Framing of the research. *In the decade between the 60s and 70s of the last century, the political debate on the environmental issue had as its central issue the relationship between economy and environment in the - increasingly evident - need to preserve the quality of the natural heritage and in the awareness that, as the planet's resources tend to be exhaustible, the models of socio-economic development should be reviewed and balanced (de Magalhães, 2023). In response to this need, the World Commission on Environment and Development introduced the concept of sustainable development in 1987 (Smyth, 2008); in the Brundtland report the concept was defined as "...development that meets the needs of the current generation without compromising the ability of future generations to meet their own needs" (WCED, 1987). This premise highlights that the commitment to promote sustainable development is based on three fundamental pillars: the environmental, the social and the economic which to be realized have gone through various phases, culminating in the significant international initiatives of Agenda 21, the Objectives of Millennium Development (MDG) and the 2030 Agenda with the 17 sustainable development goals (SDGs) (United Nations, 2021). It is a globally shared commitment among all nations aimed at eliminating poverty and other conditions of deprivation. The main goal is to combine strategic actions to improve health and education, reduce disparities and promote economic growth (Kanapathy et al., 2019).*

At the same time, this commitment is aimed at jointly addressing the challenges of climate change and ensuring the protection of oceans, forests and the environment as a whole (United Nations, 2023).

In recent years, awareness regarding sustainability issues has acquired an increasingly predominant position in global attention (Alsaati et al., 2020) as progress towards the set objectives has been slower than expected and, in some cases, the current situation is even worse than to the past: the global average temperature at the land and ocean surface during the period January-December 2023 was recorded with an increase of 1.18°C (2.12°F) compared to the 20th century average, standing at 13, 9°C (57.0°F). This is the highest overall temperature recorded globally in the period January-December 2023: each month, from June to December, recorded higher temperatures than the corresponding month of any previous year (LINDSEY R. & DAHLMAN L, 2024). Additionally, according to NOAA's 2023 Annual Climate Report, combined land and ocean temperatures have averaged an increase of 0.06°C (0.11°F) per decade since

1850, or about 2°F in total, and the rate of warming since 1982 is more than three times higher: 0.20°C (0.36°F) per decade (NOAA National Centers for Environmental Information, 2024). It is clear from the report that human activities, especially through greenhouse gas emissions, have undeniably contributed to global warming, causing global surface temperatures to exceed 1.1°C above 1850-1900 levels in the period 2011-2020 (NOAA National Centers for Environmental Information, 2024). The future level of global warming will be determined by the amount of carbon dioxide and other greenhouse gases released in the coming decades. Currently, our activities, such as the burning of fossil fuels and, to a lesser extent, deforestation, contribute around 11 billion tonnes of carbon per year (equivalent to just over 40 billion tonnes of carbon dioxide) to the atmosphere. This amount of carbon exceeds the capacity of natural removal processes, leading to a steady increase in the amount of atmospheric carbon dioxide each year (Global Carbon Project, 2023). In addition, August 2, 2023 was Earth Overshoot Day, calculated every year by the Global Footprint Network using data from the National Footprint and Biocapacity Accounts (Global Carbon Project, 2023) which indicates the official exhaustion of the renewable resources that the Planet is able to offer within a year. This means that on August 2, humanity had already “finished” all the resources that nature produces in an entire year, starting to accumulate an ecological debt. With over 8 billion inhabitants, humanity consumes in excess of the planet’s natural regeneration and reabsorption capacities. In 1973, Overshoot Day fell on December 3, exceeding the annual budget by a few days. In 2003, September 12; in 2013, on August 3. The date is constantly brought forward, highlighting an increase in our ecological debt over time. Globally, we are consuming the equivalent of 1.7 Planets per year, a worrying figure that is expected to increase to two Planets by 2030, according to current trends (WWF, 2023). Over the past 5 years, the trend appears to have stabilized, but it is complex to determine whether this is due to the slowing economy or decarbonization efforts. To reach the goal set by the United Nations IPCC of reducing greenhouse gas emissions globally by 43% by 2030 (compared to 2010), it would be necessary to postpone Earth Overshoot Day by 19 days per year for following seven years (WWF, 2023).

It’s clear that no country is progressing adequately towards achieving the Sustainable Development Goals by 2030. We find ourselves in a “value-action gap”, that is, an observed discrepancy between the concerns expressed by people regarding the main environmental, social, economic or ethical and the lifestyle choices or purchasing decisions they actually put into practice (Flynn et al., 2009). In this regard, Barr & Gilg (2006) examined the gap between value and action among citizens who adopt sustainable lifestyles, such as energy saving, waste recycling, water conservation and “green” consumption. Their results highlighted significant differences not only between distinct groups (committed environmentalists, traditional environmentalists, occasional environmentalists and non-environmentalists), but also in their levels of commitment, influenced by deep social values. They also highlight that people’s predisposition to take environmental actions is rooted in and conditioned by their existing domestic lifestyle and daily experiences.

Consequently, it becomes evident that in addressing the apparent challenge of a mismatch between people’s opinions and perspectives on environmental problems and their ability and willingness to act to improve them, there are considerable conceptual and methodological challenges within academic training. Therefore, in order to achieve sustainability goals, it is essential that an individual’s perception and behaviour towards sustainability undergo a transformation, which can be achieved through education (Kanapathy et al., 2019).

The Tbilisi Intergovernmental Conference in 1977, through the Belgrade Charter, establishes the objectives of environmental education, aiming to “develop a world population aware of and interested in the environment and related problems, equipped with knowledge, skills, attitudes, motivations and commitment necessary to work both individually and collectively to resolve current problems and prevent future ones” (UNESCO, 1977).

This approach and the proposed sustainable model have been a source of inspiration for environmental educators, pushing them to constantly improve their teaching strategies and materials. The main objective of such efforts is to promote transformative action, focusing on the effective acquisition of critical knowledge and skills (Frisk E. & Larson K.L., 2011). Frisk E. & Larson K.L. (2011), in the field of environmental knowledge, identifying three distinct areas: declarative, procedural and effective knowledge. Declarative knowledge deals with the dynamics, interactions and impacts within the socio-ecological system; procedural knowledge includes information regarding local action strategies and processes aimed at change; finally, knowledge of effectiveness focuses on personal effectiveness and the consequences of actions taken (Frisk E. & Larson K.L., 2011).

Arguably these elements form the basis on which environmental educators should develop their pedagogical approach, working to refine teaching methodologies to ensure comprehensive learning and a deep awareness of environmental issues.

Environmental sustainability education emerged in the late 1960s, reflecting the environmental problems of the time (McKeown & Hopkins, 2003) and is regarded as an approach to teaching and learning aimed at developing knowledge and skills with a particular focus on behavioural change. At the heart of this approach is participatory and active citizenship, based on joint and co-created solutions, independent and autonomous thinking and learning to face a reality of change and uncertainty. The learning process can be conceived as transformative, mediated by a critical, open, pluralistic and democratic approach. An action competence approach aims to develop students’ ability, motivation and desire to play an active role in finding democratic solutions to the problems and challenges of environmental sustainable development (Brudermann et al., 2019).

The literature on sustainable learning is predominantly composed of studies that evaluate the behaviours reported by students or, in the best case scenario, explore their willingness to engage in pro-environmental actions (Malandrakis, 2022); however, the number of studies that effectively cultivate and promote students’ concrete and real-world action towards sustainability is limited (Bonnett, 2023).

This implies that the objective of Environmental Sustainability Education is not limited to a simple behavioural change in students but, rather, represents a teaching and learning process that enhances students' knowledge, skills and competences in sustainability (Bopardikar et al., 2023), resulting in a transformation in the way we think, feel and act regarding environmental issues and sustainable development (Alam, 2023).

Through sustainability education, we not only increase knowledge on this dimension, but also evaluate the perception of it and actual sustainable behaviours, in order to stimulate behavioural change towards sustainable consumption (Alam, 2022; Uralovich et al., 2023).

Environmental sustainability education could contribute to greater environmental knowledge, understood as the general understanding of facts, concepts or relationships regarding the surrounding environment and its ecosystems (Gericke et al., 2019; Mohiuddin et al., 2018) implying the understanding of fundamental relationships that can influence impacts in the surrounding environment. This could influence the perception of environmental sustainability, i.e. the mental process of individual interaction with the environment mediated through perceptive mechanisms and, in particular, cognitive mechanisms in the process of building environmental value for each individual (Vincenzi et al., 2018). The term "perception" refers to the act, process and result of actions related to understanding and interpreting a fact, phenomenon or reality. In this context, "realizing" a fact implies the ability to select it carefully, deepening its understanding rather than treating it superficially. Environmental perception can be described as a psychosocial phenomenon in which cognitive and emotional functions are involved in the representation of the environment, both at an individual and collective level (Schiano et al., 2020). Perception, therefore, constitutes the starting point in the process of acquiring knowledge, influencing both theoretical aspects and practical applications (Schutte & Bhullar, 2017).

The study of perception offers us multiple angles of approach, examining the processing process triggered by physical, chemical, environmental, social, psychological and emotional stimuli and considering effective, cultural and cognitive aspects (Kang & Bodenhausen, 2015). Similarly, one can analyse perception across various dimensions, ranging from subliminal perception to broader perceptual awareness, or from self-recognition (in one's inner world) to awareness of one's surroundings (in the outer world) (Schäufele & Hamm, 2017). It's important to underline that the connection between reality and perception is far from immediate (Chemero, 2003): the perceptual experience of an object does not represent a faithful copy of reality but, rather, a subjective representation, always limited and partial. According to Bronfenbrenner U. & Morris P. (1996) perception constitutes the set of processes that allow us to recognise, organize and give meaning to sensations coming from environmental stimuli. It's important to underline that these stimuli can originate from both the internal (individual) and external environment. In this context, sensations are processed and combined to form a mental representation of a perceived stimulus. Perception, being part of a cognitive process, does not develop in an isolated way, but is interconnected with other aspects of development such as affective, social and organic ones (Kang & Bodenhausen, 2015). Therefore, perception is closely linked to intelligence, a key element in the formation of concepts and in relation to beliefs, values, preferences and experiences (Gazzola et al., 2020). Furthermore, Gibson proposes a traditional definition of perception, which represents the extent to which environmental objects provide an information structure that ultimately reaches sensory receptors, leading to the internal identification of the object (Rookes P. & Willson J., 2005). His theory of direct perception, known as the ecological model, introduces the concept of affordances and argues that humans do not require superior cognitive processes to evaluate sensory and perceptual experiences. On the contrary, according to Rookes P. & Willson J. (2005) the perceptual process involves the construction of an initial internal representation of the stimulus, integrating sensory information with other sources of knowledge. In this context, learning takes on an important role; perception therefore becomes a dynamic process during which various hypotheses are formulated based on three main factors: sensory data, i.e. information coming from the senses; stored data, information previously acquired and retrieved from memory; constructed data, information inferred when cognitive processes operate at a higher level (Rookes P. & Willson J., 2005; Wagman J.B. & Blau J.J., 2019).

To optimize the effectiveness of perception, the environment must have an impact on the observer, manifesting itself with motivating or repulsive tones and giving this dynamic a level of emotional involvement (Wagman J.B. & Blau J.J., 2019): our mind organizes and represents sensory experiences, arising from perceptions captured through the senses, in a process in which vision stands out as a selective and creative process, intertwined with smell, touch, taste and hearing. No perception presents itself in a neutral manner; it is susceptible to both internal and external influences (Rookes P. & Willson J., 2005). Much of the perceptual process occurs unconsciously, starting from the assimilation of data, passing through representation, object recognition, the influence of the senses and perceptive judgments (Rookes P. & Willson J., 2005).

The perception of sustainability can have a significant impact on people's sustainable behaviours (Gazzola et al., 2020; Schäufele & Hamm, 2017). When people are aware and understand the importance of sustainability, they show a greater propensity to adopt behaviours aimed at reducing environmental impact and promoting sustainable practices (Kang & Bodenhausen, 2015). To fully understand this statement it is useful to analyse the theory of planned behaviour (Ajzen, 1991) which represents one of the most influential theories in predicting rational behaviour, founded on the theory of reasoned action (Fishbein & Ajzen, 1997). The latter maintains that an individual's intention to perform a certain behaviour is influenced both by his attitude towards that behaviour and by a subjective norm, relating to the perception of how others see his action. The resulting behavioural intention determines the actual execution of the behaviour.

Focusing on environmental behaviours, Hines et al. (1987) formulated the REB model, i.e. the model of Responsible Environmental Behaviour which explains how an individual's intention to act responsibly towards the environment depends mainly on a set of cognitive and personal variables, including knowledge of environmental issues, understanding of action strategies combined with implementation skills, attitudes, locus of control and personal responsibility. The intention, therefore, will result in effective environmentally responsible behaviour, unless situational factors prevent the individual from acting in accordance with that behaviour (Hines et al., 1987).

The concept of sustainable behaviour represents a global approach that promotes consumption aimed at preserving, protecting and promoting the well-being of the planet (Fabio & Croce, 2024; B. Wang & Udall, 2023). Sustainable behaviours are actions aimed at reducing the use of natural resources in products, contributing to a lower environmental footprint (White R. L. et al., 2019).

In the field of psych-environmental studies, researchers have examined several sustainable behaviours, including recycling, composting, waste management, water conservation, energy saving practices, reading about environmental topics, and participating in planning and eco-sustainable construction, as well as the conservation of ecosystems, among others (Vesely et al., 2022; Q. Wang et al., 2023). The authors specifically identify three phases of sustainable behaviour faced by consumers: the purchasing phase, the consumption phase, and the disposal phase. At the purchasing stage, consumers can choose eco-friendly products, opt for used items or consider rental options. In the consumption phase, behaviours aimed at reducing the overall consumption of resources (for example, electricity, water, energy) become relevant. In the disposal phase, recycling is the most consolidated behaviour (Vesely et al., 2022; Q. Wang et al., 2023).

Consistent with the analysis of students' knowledge, perception and behaviour towards sustainability, the Science of Sustainability (Sipos et al., 2008) highlights that the Head, Hands and Heart (HHH) approach is configured as a methodological paradigm that can be adopted by educators to evaluate performance of the students.

This multidimensional approach is designed to comprehensively capture the interconnection between the cognitive dimension (the "head"), the psychomotor dimension (the "hands") and the emotional dimension (the "heart") of students in the context of issues related to sustainability. In this regard, Klapper & Fayolle, 2023 speak of "sustainable transformative learning" emphasizing the educational experience aimed at the metamorphosis of the students' personality, directing it towards a mentality and behaviour oriented towards solving the challenges that require social restructuring. The term "sustainable" is introduced because, through this process, students develop the ability to apply new skills in activities that respect the principles of environmental, social and economic sustainability; in other words, they become agents of improvement in the world, acting more effectively and oriented towards the common good, developing a perspective that redefines the way we address problems (Klapper Rita & Zitek A., 2023).

To achieve these objectives, three different types of pedagogical activities can be used, highlighting the operational and emotional dimensions of learning: art-based creative activities to stimulate students' creativity and encourage artistic expression as a vehicle for the learning process; practice-based activities to connect theory to concrete experience, allowing students to apply their knowledge in real situations; contemplative and reflective activities to develop students' emotional awareness and understanding (Klapper, 2022).

Through this approach we intend to provide a complete education that involves students in a meaningful way, stimulating their creative, practical and emotional faculties.

Purpose of the paper. Universities are the main drivers for promoting understanding of sustainability and shaping tomorrow's leaders for a sustainable future for all (Msengi et al., 2019) through research, teaching and practices (Brudermann et al., 2019).

The achievement of sustainable scenarios depends on the individual ability to make changes that favour behaviours that are less harmful to the environment. To effectively promote such changes, it is essential to understand the self- and context-perception of individuals who adopt behaviours related to environmental sustainability. A more in-depth analysis of these self-perceptions and perceptions of the environment adds value, offering foundations for interventions aimed at promoting a sustainable environment.

Therefore, this study aims to examine in detail the level of knowledge of sustainability of university students, exploring the economic, environmental and social dimensions. A key objective is to analyse the gap between the values declared by students and the actions actually taken regarding sustainable behaviour. The research will focus on identifying individual perceptions of environmental responsibility and the actual adoption of sustainable practices. It will be assessed to what extent the students, by participating in a series of seminars on sustainability, integrate and translate the principles learned into concrete actions, contributing to the process of transformation towards a more sustainable lifestyle. It is imperative to integrate aspects of sustainability into academic education, allowing students to fully understand the impact of their daily actions on environmental degradation. This integration also fosters a critical awareness of the intrinsic link between environmental, economic and social issues, pushing students to actively influence their environment as responsible citizens, both locally and globally (Tang, 2018). In this context, universities play a crucial role in helping to solve one of the pre-eminent challenges for a sustainable future (Azhar et al., 2022).

Methodology. In order to explore students' knowledge, perception and behaviours related to environmental sustainability, our study focuses on the implementation of a training approach that highlights active and contextualized learning. The proposed series of seminars integrates elements of investigation, planning, action, evaluation and reflection, with the aim of informing and increasing students' awareness, in line with the Head, Hands and Heart (HHH) methodological approach. For the investigation phase, a questionnaire was administered to a sample of 150 students before, during and after the series of seminars, focusing on CSR issues, in particular on individual environmental responsibility. The designed questionnaire includes a total of 30 closed-ended questions, divided into four sections:

demographic profile, knowledge of sustainability (7 items), perception of environmental sustainability (9 items) and sustainable behaviours (9 items). Each item was rated using a 7-point Likert scale, where 1 = strongly disagree and 7 = strongly agree. The measurement of knowledge on environmental sustainability involved items taken from the Questionnaire on Sustainability Awareness (Gericke et al., 2019) and Sustainability Knowledge regarding eco-friendly vehicles (Mohiuddin et al., 2018). Students' perceptions were assessed using an adapted version of the Environmental Attitude Questionnaire (EAQ) by Tuncer (2008), already validated in the literature. Finally, sustainable behaviours were measured through the scale developed by Gericke et al., (2019) and, subsequently, by Fabio et al. (2024).

It is planned to conduct a study on environmental sustainability involving Italian participants. For data collection, we intend to use Microsoft Forms to create an online questionnaire in Italian. This survey will be disseminated among university students through e-mail transmission, with encouragement to participate and provide their valuable contribution. In the invitation message, an opportunity for direct communication with our research team will be included, with an invitation to students to contact us for any clarification, additional questions or further explanation regarding the questionnaire. Active collaboration with participants will be essential to ensure the quality and completeness of responses, as well as promoting informed and conscious participation in the study.

Results. Sustainability education activities are aligned with the United Nations Sustainable Development Agenda, in particular with Goals 4 and 13, which aim, respectively, to ensure inclusive and equitable quality education and promote lifelong learning opportunities for all and take urgent measures with substantial impact to combat climate change and its consequences.

This research is conducted to evaluate students' knowledge, perception and behaviours towards sustainability. The main attention was paid to reducing the gap between knowledge on sustainability issues, students' perception of sustainability and their actual behaviours in daily life. Through a program of seminars on environmental sustainability education, the research offers a useful starting point for evaluating the positive effect of sustainable initiatives promoted by universities. A solid connection between seminar participation, perception of sustainability and actual sustainable behaviours is highlighted, indicating the importance of understanding sustainability issues and approval of sustainable programmes.

The analysis of the effectiveness of the seminars focuses on how much the students internalize and translate the principles learned into concrete actions, including expected changes in knowledge, attitudes and behaviours after participation in the seminars. This perspective reflects effective sustainability education, characterized by holistic systems, an ability to create connections, interdisciplinarity and lateral rigor guiding students towards more sustainable practices. Indeed, it is expected that students, through effective participation, will be able to connect sustainability issues to current realities and show a positive attitude in implementing sustainable behaviours to improve the present and future conditions of the planet.

Research limitations. This investigation highlights some limitations. First of all, it's crucial to recognize the limited nature of the sample under study, currently limited to students of the University of Salerno. A further aspect to take into consideration is the voluntary nature of the responses and the possible associated bias, since the use of online surveys could mainly attract students already predisposed or sensitive to the topic of sustainability, with the possibility of introducing a potential distortion in the results.

Managerial implications. The managerial context linked to research entails various challenges and opportunities, requiring an integrated and strategic approach. First of all, it's essential to highlight the importance of integrating sustainability into academic training: universities, as centres of knowledge, must take a leading role in the training of aware and sustainability-oriented professionals, implying not only the inclusion of environmental, economic and social aspects in academic programs, but also the active promotion of courses dedicated to these issues. In parallel, encouraging student engagement emerges as a key element. Encouraging the active participation of students in programs and seminars on sustainability is essential, but even more significant is involving them in practical projects, project work, internships, seminars, the creation of clubs or student associations dedicated to sustainability can promote collaboration and offer students a fertile ground for transforming theoretical knowledge into concrete actions in order to align the behaviours of human beings with the sustainability objectives of the 2030 Agenda. To date, sustainable skills must be at the centre of educational programs, preparing students to face challenges current and future and contribute positively to society.

The adoption of sustainable policies and sustainable practices at the institutional level, engaging faculty, staff and students in a common commitment, is essential to transform universities into effective catalysts for sustainable development.

Originality of the paper. The originality of this research lies in the multidimensional approach adopted to examine environmental sustainability, which also embraces economic and social dimensions. Thanks to an in-depth analysis, we aim to obtain a more detailed and nuanced understanding of sustainability. A distinctive element is represented by the investigation into the gap between the values declared by students regarding sustainability and the actions actually carried out. This approach aims to evaluate the actual transformation of declared intentions into concrete behaviours, thus offering a realistic perspective on the actual individual commitment towards sustainability.

A further point of value, in particular for future research, consists in the prospect of conducting the investigation not only in Italy, but also in other European countries, adopting a cross-cultural perspective in order to highlight cultural variations in knowledge, in values and behaviours related to sustainability. This analysis could identify any cultural

variations in perceptions and behaviours related to sustainability and, therefore, provide valuable insights for effectively adapting educational strategies in diversified contexts.

Understanding the link among cultural participation, resilience, and well-being. A systematic literature review.

GIORGIA MASILI¹ DANIELE BINCI²

Abstract

The scientific community is increasingly aware of cultural participation's role in enhancing the well-being of individuals and communities. Our paper aims to provide a more comprehensive understanding of this role through a systematic literature review that follows the PRISMA approach and sets future research and policy development directions.

Keywords: *cultural participation; cultural engagement; well-being; subjective well-being; resilience*

Aim of the paper. *The prosperity of a community can be characterised as a collective advantage for all its members, indicating the attainment of sufficient economic progress and the consequent favourable perception of individuals regarding their rightful position within society, exemplified by their quality of life (Ivković et al., 2014). The concept of well-being (Ryff et al., 2021) is considered a multifaceted (D'Agostino et al., 2019) and multidisciplinary concept which embraces several disciplines, from philosophy to psychology, economics, healthcare, and education (Burr and Floridi, 2020; Das et al., 2020). It is a complex concept which involves "cognitive and emotional evaluations, driven by objective as well as subjective factors" (Addis and Rurale, 2024, pag. 3). Indeed, the existing body of literature identifies two dimensions of well-being: objective well-being (OECD, 2013) which can be seen as an outcome and a reflection of tangible living conditions, and subjective well-being (Diener, 1984;2018; Kapteyn et al., 2015) generally identified as the perception of individuals on their living conditions (Alatartseva and Barysheva, 2015). Moreover, the psychology literature distinguished between two main approaches to well-being: hedonic and eudaimonic (Ryff et al., 2021; Waterman 1993). The hedonic approach is connected to pleasant and unpleasant experiences in life, and its components are represented by life satisfaction and positive and negative effects. On the other hand, the eudaimonic approach (Ryff & Singer, 2008) includes different dimensions such as self-acceptance, positive relations with others, environmental mastery, autonomy, and personal growth which are related to the "different challenges that individuals encounter as they strive to function positively" (Ryff et al., 2021, pag. 97).*

Today, scholars have increased their interest in the role of art and cultural participation in individuals' well-being as they can be crucial for enhancing it (Fancourt and Finn, 2019; An et al., 2022). Cultural participation can be identified as a comprehensive term which has constantly broadened its scope to incorporate an evolving range of activities, driven by shifts in social and cultural dynamics (Murray, 2006). It can be seen as the act of engaging in various cultural activities (Stevenson et al., 2017) and experiences and it acknowledges the audience as an engaged conversational partner, to be consulted or included in the process of planning and crafting the cultural offerings (OECD, 2022). It can be expressed with active or passive involvement (Passaretti et al., 2023). Through active involvement, individuals directly contribute to creating the cultural experience itself, while the passive form concerns the enjoyment of experiences and content crafted by others (Grossi et al., 2011). However, the lack of a wider and more comprehensive definition obstacles the policymakers in promoting new active forms of cultural participation that can have a significant social and economic impact (Sacco et al. 2018). Several studies underline the positive impact of cultural participation on individuals' overall well-being and subjective well-being in particular (Reyes-Martínez et al., 2021;2023; Blessi et al., 2016). Indeed, although culture might not explicitly dictate life expectancy or physical well-being, its influence on individuals' well-being is significant. It can enhance resilience (Wagnild, 2009) and contribute to developing lively and thriving communities (Grossi et al., 2011). Engaging in cultural activities encompasses the diverse methods and expressions through which individuals can avail themselves of cultural artefacts and encounters (OECD, 2022).

Through a systematic examination of existing literature, our paper strives to offer a more thorough comprehension of cultural participation's impact (especially about active involvement) on individuals' well-being by answering the following research question: What is the role of cultural participation in individuals' well-being?

Methodology. According to Moher et al. (2015;2009), we developed a systematic literature analysis by adopting the PRISMA approach, which follows four main steps: identification, screening, eligibility, and inclusion. Such an approach proves beneficial for examining, summarising, and conceptualising pivotal themes and emerging topics, encompassing their implications for future research. First, we developed the research by adopting the Scopus search engine, from which we collected the articles. Two sets of keywords related to “cultural experiences” and “well-being” were selected and combined to conduct the research. The first set of keywords included terms such as “cultural experiences”, “cultural consumption”, “cultural engagement”, and “cultural participation” as they were related to the aspect of cultural experiences consumption. The second set of keywords was based on individuals’ well-being under cultural consumption, and it included terms such as “well-being”, “eudaimonia”, “hedonic”, and “quality of life”, Refining and combining the keywords in the two blocks allowed us to identify 281 studies.

In the second step, according to the screening criteria, we collected articles written in English that had already been published. We considered articles published in social science, business management, and psychology between 2010 and 2024 (Figure 1). The choice of including articles in the psychology field of research is related to the multi-disciplinarity of the research on well-being. Accordingly, we identified and selected 113 documents.

The third step included analysing the abstracts to ensure that only those strictly related to the topic of cultural consumption and well-being were considered. Therefore, 29 articles were excluded as irrelevant, and 84 articles remained for the literature review. Then, each author independently analysed the sample of 84 articles to ensure their eligibility according to the study’s goals. Through the full-text analysis, 8 papers were excluded as irrelevant.

In the fourth and final step, we validate each article according to the study’s goals, identify the leading research categories and trends and formulate recommendations for future studies (Bretas & Alon, 2021).

Figure 1 - Time span of articles distribution

Source: author’s elaboration on Scopus data

Findings. In this section, the authors present the descriptive analysis of the selected papers. A dedicated analysis of the 76 full articles identified was developed to ensure that only the articles related to well-being and cultural participation were included. All of them were pertinent to be examined to synthesise the results identified, presenting the interpretations associated with the paper’s subject matter. More in detail, as clearly visible in Figure 1, the majority of the scrutinised articles were published between 2020 and 2023, underlining a pick in publications in 2021, signifying an increasing interest in the topic of well-being in connection with cultural participation and experiences.

Following the Scopus database classifications, the articles were reconducted to subject areas, as shown in Table 1. The most populated categories are related to studies in social science and psychology. However, due to the multidisciplinary nature of the topic under study, several articles were conducted under the category “others,” which outlines the fragmentation of the literature and the different perspectives adopted in studying the phenomenon.

Table 1 - Distribution of the paper across areas

Type of Journal	Number of articles	%
Social science	23	30,26%
Psychology	20	26,32%
Arts and Humanities	7	9,21%
Sustainability	6	7,89%
Business, management	5	6,58%
Economics	4	5,26%
Urban Studies	3	3,95%
Others	8	10,53%
Total	76	100,00%

Source: Authors’ elaboration

The articles analysed were categorised based on their typology (theoretical or empirical) and according to the methodological approach adopted, as indicated in Table 2. Most of the articles identified conducted quantitative empirical analyses, followed by qualitative empirical and mixed-methods articles. The lack of literature review studies on the topic makes our contribution coherent and useful.

Table 2 - Distribution of the paper across research methodologies

Type of paper	Method	Number of articles	%
Theoretical	Literature review	2	2,63%
	Conceptual paper	1	1,32%
Empirical	Quantitative	44	57,89%
	Qualitative	18	23,68%
	Mixed Method	11	14,47%
TOTAL		76	100,00%

Source: Authors' elaboration

Thematic analysis. The first general evidence from the thematic analysis conducted on the selected articles confirms that participation and consumption of cultural activities and cultural engagement contribute to human/individuals' well-being in different forms, as underlined in past studies. Indeed, participation in cultural activities and frequenting cultural sites (e.g., museums, galleries, theatres, sports events, etc.) represent important elements for enhancing well-being in terms of mental illness, self-realisation and life satisfaction not only in young generations but also in older adults (Crociana et al., 2014; Tymoszyk et al., 2019).

The second important piece of evidence concerns the role of cultural participation and access to art during the pandemic. Indeed, a group of studies highlight how online engagement that was possible due to the adoption of technologies by cultural institutes and the promotion of online activities, events, etc., contributed to the enhancement of the well-being of individuals and continued producing benefits also during the period of transition back to in-person engagement (Mak et al., 2021; Anisimovich et al., 2022). Indeed, adopting technologies to bring cultural contribution to the virtual environment stimulated curiosity and transformed the interaction between arts and cultural institutes and their public underlining. Online cultural engagement in several forms has represented a fundamental tool to contrast the state of anxiety and loneliness and enhance individuals' well-being during the pandemic lowering the fear related to its negative impact (Trupp et al., 2022; Gotthardt et al., 2023). Virtual access to culture and arts stimulated people to engage online and benefit from the positive impact on their mental health and well-being deriving from that experience. The positive effects also lasted after the pandemic, especially for individuals with limited access to onsite events or activities. Indeed, virtual access favoured connectivity with other communities by enriching the in-persons' experience and encouraging a deeper connection in local culture (Caiola et al., 2023) but also demonstrating the crucial role of cultural activities and participation in arts for processing trauma (Anisimovich et al., 2022). These studies underline that if online engagement is well supported by interesting and meaningful content, it "inspires cognitive-emotional states in the viewer" (Trupp et al., 2022). In particular, the strongest predictors of engagement in arts during the pandemic are identified in age, education attainment, social support and emotion-focused or supportive coping styles and show evidence of the fact that engaging in arts activities represented for most individuals a strategy to cope with the negative emotions indicted by the pandemic and to improve self-development and resilience increasing their well-being (Mak et al., 2021; Chapple et al., 2023).

The third important piece of evidence emerging from the analysis of the literature concerns the fact that having access to arts and culture contributes to building social cohesion, identity, a sense of belonging and increasing well-being (Piscitelli, 2020). Accordingly, the importance of developing adequate policies to support subjective well-being by leveraging the promotion of cultural activities is highlighted. Indeed, facilitating access to arts and supporting engagement in art and culture might enhance the subjective well-being of individuals and communities (Anisimovich et al., 2022). Moreover, culture-based public health programs and policies and the adoption of innovative strategies in designing welfare policies are described as potential fundamental tools for enhancing well-being (Crociana et al., 2014; Grossi et al., 2019). Policy development should promote engagement in arts and culture consumption at different stages of individual lives. Indeed, when engagement in art and cultural consumption begins very early in life, it is more likely to continue (Espinosa et al., 2021). However, participating in such activities correlates with increased levels of education, improved socioeconomic status, and a reduced incidence of health issues (Tymoszyk et al., 2019). Therefore, investments in cultural education and effective policies to reduce inequalities in accessing cultural activities and art consumption might foster engagement and positively impact individuals' well-being.

Research Limits. The limitations of our paper mainly relate to the criteria adopted in the selection step. Indeed, by circumscribing to specific study areas, focusing only on articles written in English, and excluding sources of evidence such as conference papers, book chapters, etc., we might not have considered other potentially relevant sources of evidence. In addition, at this stage, this paper shows some of the evidence from the analysis of the articles since the process of analysis is still under development. Moreover, this explorative study considers cultural activities in general.

We need to analyse and focus on different cultural activities and how they differently impact subjective well-being and other important outcomes.

Theoretical and practical Implications. Our paper contributes to the analysis of the link between cultural participation, resilience, and well-being. The multidisciplinary nature of the studies on well-being shed light on the necessity of better understanding the contribution derived from various fields of research and the importance of cultural participation. Therefore, the summarisation of the current literature concerning the role played by culture in increasing individuals' well-being can represent a point of departure for scholars to identify future research insights and advance new contributions. Moreover, by clarifying the role of participation in cultural activities and art in increasing individuals' well-being, it might be possible to suggest guidelines for policymakers and organisations involved in the sector. From a practical point of view, we suggest that participation in cultural events should be fuelled both online and in-person, according to the specific needs of the target markets. Given the potential positive benefits of cultural participation both for new generations as well as older people, it is important to enable virtual and traditional opportunities for target users to benefit from culture and art.

Originality/value. Few literature reviews have been conducted on the relationship between well-being, resilience and cultural participation. This Systematic Literature Review offers a broad view of those studies focusing on the impact of cultural participation on individual well-being. By considering the multidisciplinary nature of well-being, we adopted a holistic approach that considers studies in several disciplines, such as management, psychology, and social sciences. This approach allows us to have a cross-disciplinary overview of the phenomenon, collecting different elements that can be insightful to set up guidelines for policymakers and companies that work in the cultural sector aiming at improving their social impact on society and increasing individuals' and communities' well-being and resilience.

Shaping tomorrow's sustainable enterprises: profiling the hard and soft skills of sustainable managers

GIULIA NEVI¹ GIULIA GOGIALI² GIANPAOLO BASILE³ LUCA DEZI⁴ CARMELA GUITTO⁵

Abstract

Despite the growing importance of sustainability in the enterprise, a knowledge gap exists regarding the specific roles and skills of professionals managing it. This research explores the key characteristics and differences between three sustainability professions: CSR Manager, Sustainability Manager, and ESG Manager. Employing a qualitative approach, the study conducts a content analysis of job advertisements for each position (n=146) posted on LinkedIn and similar platforms between June and September 2023. The analysis aims to identify the main hard and soft skills companies demand when seeking these sustainability professionals. This research sheds light on the evolving landscape of corporate sustainability management, offering valuable insights for companies seeking qualified personnel and individuals aspiring to enter these fields. It is also a study that opens critical reflections on what may be new professional figures that will emerge to manage the challenges of the near future such as the stakeholder manager and the ecosystem manager.

Keywords: ESG manager; CSR manager; Sustainability manager; Ecosystem Manager, Stakeholder Manager; Human resource,

Framing of the research. Several scholars, including Rasoulinezhad (2020), Zakari et al. (2022) and Sun et al. (2023), agree that the future well-being of humanity depends on the adoption of sustainable development practices. They argue that any alternative to sustainable development undermines economic stability and exacerbates the depletion of natural resources, increasing the threats of global warming and climate change. For this reason, companies are showing an increasing interest and focus on environmental and social issues, especially concerning ethical and responsible corporate behaviour (Baumgartner & Winter, 2014). Corporate Social Responsibility (CSR) is a governance tool that facilitates a possible 'match' between organizations and their stakeholders. CSR represents a strategic approach aimed at two goals: taking charge of the harmful effects and being aware of the social dimension of the organization, contributing to answering community needs. The business models are increasingly configured as "stakeholder-based," demonstrating that businesses dealing with competitive, environmental, and social challenges must create and manage bidirectional relationships with heterogeneous actors. This trend offers a framework and guidelines to ensure that the company acts responsibly towards and with its internal shareholders, employees, and other stakeholders, such as the local community, suppliers, customers and the environment (Del Baldo, 2010; Sciarelli, 2002). CSR aims to create value for communities and companies, improving social legitimation and reputation, investor trust and employee satisfaction (Van de Ven, 2008; Skudiene and Auruskeviciene, 2012). The evolution of the concept of sustainability and the adoption of more responsible business practices have led to new conceptualisations such as the ESG pillars - Environmental, Social, and Governance, in which, unlike CSR, it considers financial and non-financial performances as the company's objectives (Galbreath, 2013; Gillan et al., 2021). The pillars of ESG are also born with the hope of measuring companies' environmental, social, and governance performance through standardized and shared metrics; despite that, the road is still long, so the impact of taking ESG criteria could create real value. This was an obstacle since the results could not be measured or compared, as they were subjective. The concept of ESG has a vast literature but still with considerable research potential (De Falco et al. 2024). Faced with thus having to cope with new and sought-after sustainable needs, companies have discovered themselves bereft of professional figures capable of meeting them. New professional figures

⁵ Sapienza University of Roma
e-mail: guitto.2020194@studenti.uniroma1.it

have naturally responded to these new needs, duties and rights (Camargo et al., 2023). Thus, in addition to the CSR, we have the ESG Manager, who is in charge of guiding and implementing environmentally, socially and governance-oriented corporate strategies (Munoz et al., 2014; Van Duuren et al., 2016) and the Sustainability Manager (SM) (Borglund et al., 2023), who represents the highest-ranking position within the organisation dedicated to overseeing sustainability initiatives. Its emergence reflects the increasing significance of corporate social responsibility (CSR) and sustainability within the business landscape (Wright et al., 2012; Borglund et al., 2023). Such professions require specific skills; they are crucial in ensuring effective business operations management and creating long-term value. In this context, we speak of soft and hard skills. Soft skills refer to skills or behavioural personality characteristics manifested in everyday life (Mohd et al., 2024). They can be described as knowledge inherent in the human mind and very personal, involved in experiences, actions and ideals (Chen et al., 2018). These skills are fundamental to preparing for work and include communication skills, thinking skills, creativity, leadership, problem-solving, management, continuous learning and teamwork skills (Mohd et al., 2024; Cimatti, 2016). On the other hand, hard skills are associated with the ability to use specialised tools, procedures and techniques (Ahmad et al., 2020; Cimatti et al., 2016). These competencies are required to apply specific knowledge and skills in a real work context.

Purpose of the paper. There has been no shortage of changes concerning job positions, which have increasingly evolved to the development of new figures at the managerial level: the sustainability manager, the CSR manager, and the ESG manager, each with their responsibilities, tasks, and skills. Despite the importance of these figures in the corporate landscape, there still needs to be more knowledge regarding the qualifications, job responsibilities and hard and soft skills of professionals in charge of strategic corporate sustainability management (Macdonald et al., 2020). This paper aims to answer the research question: "What are the main characteristics and differences between the new professions called upon to manage sustainability: CSR manager, Sustainability Manager, and ESG manager?"

Methodology. In answering this research question, a qualitative approach was adopted by conducting a content analysis to map the skills of the three professional figures listed: the CSR manager, the sustainability manager, and the ESG manager. To analyse and deepen the phenomenon, research was carried out on specific job offers for each of the 3 relevant figures: Sustainability manager (n =50), ESG manager (n=47), and CSR manager (n=49), to identify the main skills required by companies. Offers published on LinkedIn or other professional search channels from June to September 2023 were investigated.

Results. An initial review shows that these figures must possess many competencies, including leadership, problem-solving skills, transparency, and teamwork, to successfully address sustainability challenges (Borglund et al., 2023). Now, we present the characteristics specific to each analyzed figure.

The "CSR manager" is responsible for developing CSR-oriented corporate strategies that align with the company's values. His or her role is to ensure that a company operates in a socially responsible manner, contributing to and positively impacting the environment. From our analysis, the CSR manager is not only required to have a degree in STEM subjects, but companies also expect him/her to be a doctor in communication to support the disclosure activities. The role of the CSR manager generally covers these responsibilities: 1. strategy development; 2. stakeholder and community engagement; 3. reporting; 4. communication; 5. business integration. The online research work for the CSR manager, on the base of 49 announcements (4 companies of human resources; 6 employment agencies; 8 agencies specialising in fashion and clothing; 6 agencies operating in the energy and environment sector; 4 companies operating in the large-scale distribution and organized production of goods and products; 21 other sectors). The Main Hard skills aspected are knowledge of the English language (n=36); a university degree (n=30); knowledge of the Office package (n=15); knowledge of relevant regulations and new taxonomies on environment issues but not confined them knowledge of GRI standards (n=13), finally know how to develop reports and CSR principles (n= 6). Soft skills, in order of importance, are communication and interpersonal skills (n=24); problem-solving skills (n=18); teamwork skills (n=15); flexibility and proactivity (n=10); curiosity, interest and passion for the subject (n=8); possession of analytical skills (n=9); time management (n=3).

The "sustainability manager" is a new figure that has emerged recently. When creating a 'sustainable' corporate strategy it became a managerial task and was no longer carried out at arm's length. Initially, this figure only dealt with sustainable reporting and the sustainability report; today, these are only some tasks he or she performs. At first, therefore, it was internal figures within companies who showed a strong interest in the topic of sustainability. During the period in analysis, 50 announcements were posted for the position (9 consulting and business services companies; 4 consulting and it services companies; 7 human resources services companies; 2 financial services companies; 11 personnel services and recruitment companies; 18 miscellaneous services companies, such as professional services, real estate, freight transport). Today, following a path of increasing development, the Sustainability manager has reached a managerial role, with specific skills and tasks to deal with all environmental, social and economic issues to build the company's business strategy. Thus, his role in the company has a twofold objective: developing various reports, mainly related to sustainability reports, and defining the business strategy from a sustainable perspective. These two objectives are increasingly complex as the company itself grows. The Main Hard skills required are knowledge of the English language (n=36), degrees in STEM subjects (n=43), knowledge of ISO standards (n=22), knowledge of the Office package (n=15), reporting skills (n=8); to a lesser extent, the following are required experience in sustainability reporting (n=8), experience with Autocad (n=5), possession of other sustainable certifications (n=3). The main soft skills to take into account are teamwork (n=25), problem-solving (n=18), communication (n=21), passion and leadership qualities (n=7), critical and analytical thinking (n=3), and goal-oriented (n=3). The sustainability manager is a specialist who carries out the task of transforming the company into a sustainable reality, managing the company's environmental, economic,

and social impact, and ensuring that the business is sustainable in every respect. She/He aims to optimize the company's processes in compliance with laws and regulations and to research new sustainable initiatives. He achieves this by meeting three thematic requirements: understanding the evolution of ESG standards and their impact on market dynamics, driving the evolution of environmental systems towards sustainability, and promoting a CSR corporate culture.

The 'ESG manager', defined by the Randstad platform, is a professional who develops strategies that impact the environment, society and corporate governance while remaining aligned with corporate values. This figure was born following the emergence and development of ESG standards in 2006. Among the many tasks he or she may be involved in, the main ones are ESG assessment and reporting, ESG integration in corporate strategies, and external ESG communication: risk and opportunity assessment. 47 announcements were reviewed (4 companies are operating in the business services sector; 11 are recruiting professionals; 4 are IT consultancy; 4 are operating in the credit and finance sector; 24 out of 50 companies are from various sectors). From this review, the Hard skills most required are English language (n=35), knowing how to analyse KPIs (n=15), knowing how to use Office Package (n=12), knowing sustainability regulations and stay up-to-date on them (n=11), know how to develop a sustainability budget and reports (n=10), know GRI standards and how to apply them (n=10), as a basis, as for the other positions, possess a master's or specialist degree with a strong interest in STEM subjects (32). Compared to other advertisements, the Soft skills required for this figure still need to be clarified. In fact, in many advertisements, they were often not made explicit. The analysis identified the following as the main ones for soft skills: teamwork (n=22), interpersonal and communication skills (n=21), problem-solving skills (n=18), being able to work autonomously (n=9), being proactive (n=8), being able to organise oneself and be a leader (n=7), having a passion for sustainability (n=6), feeling motivated (n=6).

A comparison of the three figures shows that in terms of hard skills are more specific and different, although common factors are now knowledge of English and the Office package and the most relevant ISO standards. As it emerges, the CSR manager is more oriented towards reputation and public relations management. In contrast, the Sustainability manager focuses more on reporting and certification and the knowledge of software such as Autocad. What is also interesting is how, in many cases, the differences in the skills required for these managers are determined by the sector and the size of the company that has to report or comply with specific sustainability obligations. In terms of demand for soft skills, the most in-demand are interpersonal and communication skills, the ability to work in a team and problem-solving skills.

The growing demand for these skills, coupled with the great development of platforms and networks by companies to have a sustainable view and management of the entire value chain and as posit in Argyres et al. (2019) on their theory of partnership, is possible to be prodromal to the emergence of a new professional figure that is already appearing on job platform ads such as LinkedIn.

Reference is made in particular to two new figures. The first is the "Stakeholder manager" will need to demonstrate the ability to manage broad stakeholder networks for the development of projects with primarily environmental and social impacts, be able to identify key stakeholders and be proactive in conflict resolution and the promotion of positive stakeholder involvement in the organisation or project. In addition to great critical skills, interpersonal mediation skills and resilience, it will be important to mature a "Stakeholders skill".

The second is the "Ecosystem manager" on the other hand, will be responsible for orchestrating, managing and being a voice within large innovative and non-innovative ecosystems, such a figure will not only be concerned with sustainability, but with ensuring both the growth, resilience of the ecosystem and the assessment of its impact at different levels and the safeguarding and support in the realisation of common goals among the different ecosystem actors.

Research limitations. This study suffers from particular limitations, hopefully paving the way for future research. The sample of advertisements selected is purely Italian. In the future, it will be interesting to extend the analysis to European countries or countries where interest in and legislation towards sustainability is different, e.g., emerging or more attentive and developed countries. It will then be essential to extend the research by conducting qualitative surveys to understand whether the real demand for skills is confirmed in professional practice in the tasks and activities these managers must perform. In addition, future research will have to capture any misalignment between the different figures and the skills trained by universities and other training centres. It will also be interesting to monitor how, over time and across business sectors, the three figures will change; for example, there is an increasing tendency to separate the different pillars of sustainability in administrative management, and environmental management is assigned to specific figures, more of an engineering nature, while the new diversity managers increasingly carry out social management.

Managerial implications. This extended abstract has several implications for management. The roles analysed require various skills, including leadership, problem-solving, transparency and teamwork skills. Companies should invest in ongoing training to develop these skills in their CSR, sustainability, and ESG managers. As interpersonal skills, teamwork, problem-solving, and capabilities to create and manage relations (engagement) with heterogeneous agents emerge as the most in-demand soft skills, companies should emphasise selecting and developing managers with these skills. This emphasises the importance of a more holistic approach in assessing soft skills, with particular attention to elements such as emotional management and interpersonal skills, which can substantially influence work dynamics and leadership in sustainability-oriented contexts. Coaching and mentorship programs can help improve these skills. Given the increasing complexities of the responsibilities assigned to these roles, flexibility and proactivity are essential. Work environments must foster a culture that promotes flexibility and encourages staff to stay up to date on new trends and

regulations. However, we must recognize the impact that new technologies will have in redesigning the skills and abilities required of these figures.

Additionally, all three should maintain a solid technical knowledge base, including understanding environmental regulations, managing KPIs, applying standards such as GRI, and having in-depth knowledge of ISO standards. This requires constant updating on regulatory and technological developments in the sector. On the other hand, companies will have to understand which figures are most suitable for their needs. In the future, more hybrid figures may arise to combine the different sustainability dimensions with the growing need for highly specialised figures.

As it turned out, it has been seen that to transform into agents of change in sustainable behaviors are relevant dimensions such as ethical sensitivity and pro-environment behavior (Azam 2023). The present study highlights that these dimensions of soft skills still need to be researched. In the future, therefore, one should consider whether dimensions such as commitment to sustainability and moral ethics are assessed in assessment by, for example, conducting qualitative research on human resources deputed to personnel selection as well as being ready to assess whether in filling these roles it determines a change in terms of sensitivity and decision making with repercussions on business strategies and in relations with top management.

The present paper also offers important reflections at the theoretical level; in particular scarce are the reflections on the skills and competencies that those deputed to manage sustainability in enterprises should have especially if as posit in Annosi et al. 2023 and Petriglieri and Petriglieri (2020) “managers are not born nor made but fabricated” it is relevant on how facilitate the build of more responsible and ethical manager able to manage the broader dimension of sustainability that will be mirror of the company commitment.

Originality of the paper. Faced with a growing commitment to sustainability, contemporary companies are called upon to manage and initiate new sustainable processes to comply with regulations and reporting that require specific skills. However, there has yet to be a clear survey of the hard and soft skills most required by companies. This study highlights the characteristics most in demand and the similarities and differences between the three leading figures called upon to oversee a company's sustainability. The study opens critical reflections on what may be new professional figures that will emerge to manage the challenges of the near future such as the stakeholder manager and the ecosystem manager

Virtual influencers in tourism marketing: insight or oversight? The case of “Open to Meraviglia”

GABRIELE BAIMA¹ RADA GUTULEAC² CRISTIAN RIZZO³

Abstract

Virtual influencers (VI) are increasingly being applied to different industries, extending their reach into the tourism context as well. Despite their growing popularity and use, consumer reactions to VIs are ambivalent. In particular, the Italian Ministry of Tourism’s recent ‘Open to Wonder’ project, which employed Botticelli’s Venus to promote Italian tourism, elicited a wide range of criticisms among users. The aim of this study is to investigate the underlying motives in terms of salient source (influencer-related) and content (post-related) attributes that drive Instagram users’ negative feelings. We find that inexpressive versatility, low-quality images, impersonal and inadequate caption discourse, as well as perceived lack of professionalism, significantly reduce her potential to engage with the audience. We discuss these results within the context of source credibility theory, trying to unveil the motivation underlying negative feedback from users. Managerial implications are provided with recommendations on how tourism practitioners can harness VI marketing effectively to avoid criticism from the public.

Keywords: *virtual influencers; tourism; digital communication; social media campaigns; case study; source credibility theory*

Framing of the research. *Virtual influencers are AI influencers (i.e., those generated using AI technology) computer-generated characters (i.e., created by the computer-generated imagery technology), or digital influencers/personas/entities. By engaging in activities such as modeling, socializing, post content, sharing opinions, promote brands, VIs project a human-like persona (Arsenyan and Mirowska, 2021). Consequently, capitalizing on their advantages, businesses are partnering with these entities to endorse their products and services (Campbell and Farrell, 2020; Gutuleac et al., 2024).*

Past research found that VIs are achieving different outcomes from brands in terms of attracting new audience segments, increased awareness, favorable publicity, and increased consumer engagement (Franke et al., 2023; Thomas and Fowler, 2021). Specifically, integrating VIs into a brand’s marketing strategy can position the company as innovative and tech-savvy, leading to a positive impact on its brand reputation among users (Conti et al., 2022). Moreover, virtual influencers remain permanently under the auspices of the company, thus eliminating the likelihood of any negative and unethical surprises (Deng and Jiang, 2023). In particular, companies can use VIs to enhance the credibility and authority of their product endorsements, as VIs can exclusively be created or commissioned to mirror a brand’s image and values (Yan et al., 2022; Sands et al., 2022). Due to their adaptability, they do not depend on physical and time limitations. Specifically, they can be leveraged for promotional purposes in a wide range of contexts and moments, making them an attractive option for brands seeking versatility (Ferraro et al., 2024). Although there is no lack of significant concerns (Conti et al., 2022), such as authenticity, high costs, and unrealistic expectations, these issues are generally mitigated by users’ tendency to not hold virtual influencers directly responsible for negative outcomes. Instead, they direct their criticism towards the creators or companies behind their development (Liu and Lee, 2022).

Although they are widely and profitably being introduced in product advertisements, it remains to be proven whether they are also effective in tourism sponsorship. In fact, just lively scholarly research explores the potential use of VIs in the context of tourism marketing. In this vein, Xie-Carson et al. (2023) found that humanlike VIs are preferred over 3D animated VIs and the least preferred influencers are 2D animated VIs. Furthermore, Instagram posts from humanlike VIs that combine images of tourism settings with rational messages attract the most engagement from the audience. More generally, Block and Lovegrove (2021) focused on the post content, by conducting textual and sentiment analysis on Lil Miquela’s posts and listed intriguing identity, innovative storytelling, and emotional engagement as core communication

e-mail: cristian.rizzo@unito.it

strategies. In their semiotic analysis, De Brito Silva and colleagues (2022) concluded that the most important marketing strategies of VIs depend on the alignment of their posts with their lifestyle, personality, and the narrative of their personal lives. From a consumer perspective, previous studies suggest that individuals interact with VIs as they interact with human influencers (Lou et al., 2023; Sands et al., 2022). However, some research suggests that credibility is still a significant barrier for companies using VIs (Arsenyan and Mirowska, 2021; Franke et al., 2023). In this vein, influencers' success in influencing the user's behavior depends on credibility. In the social media context, source credibility refers to the extent to which content creators are believed to be credible, knowledgeable, and trustworthy by their audiences (Zha et al., 2018). The four-dimensional definition of source credibility is composed of expertise, trustworthiness, attractiveness and similarity. Expertise signifies that the source possesses adequate knowledge and skills in a specific domain, while trustworthiness reflects the source's honesty, and integrity as perceived by the user (Colliander and Marder, 2018). Attractiveness is frequently related to the physical appreciation of the source, while similarity involves the common traits that audiences share with media figures (Yuan and Lou, 2020; Schiappa et al., 2007). For instance, Lou and colleagues (2023) found that most followers perceive virtual influencers as uncanny and authentically fake. Despite their effectiveness in enhancing brand awareness, VIs often fail to inspire purchase intentions due to their lack of authenticity, low similarity to followers, and their weak parasocial relations with followers. Choudhry et al. (2022) explain that followers' attraction to virtual influencers arises from a persuasive combination of visual appeal, mystique and innovative storytelling. However, there is a perceived reluctance to attribute trustworthiness to these virtual entities. Furthermore, Yang et al. (2022) demonstrate that virtual influencers characterized by a higher degree of perceived humanness are associated with enhanced levels of trustworthiness, expertise, and attractiveness. Here, source credibility theory is addressed to explain how the sub-dimensions (attractiveness, expertise, trustworthiness and similarity) might explain negative feedback from users.

Given that the tourism sector is increasingly influenced by influencer marketing trends, there is a significant opportunity to leverage VIs engagement to market tourism experiences. However, research into how users interact with and respond to VI marketing in the tourism industry is still lacking.

Purpose of the paper. The aim of this research is to analyze the underlying motives in terms of salient source (influencer-related) and content (post-related) attributes that drive Instagram users' negative feelings towards *VenerItalia23*, a digitally designed influencer created with the intention of promoting the international attractiveness of Italian tourism. Specifically, we intend to investigate the causal factors that contribute to the prevailing negative feedback within the campaign's reception. By conducting a qualitative assessment of the interactions and sentiments expressed by the audience, we try to unravel the underlying mechanisms that have negatively influenced public perception. The final purpose is to provide a more in-depth understanding of the complexity and potential drawbacks associated with the application of VIs in the tourism marketing context. Drawing on our findings, the study shall offer valuable recommendations for enhancing and optimizing future marketing strategies within the tourism context.

Methodology. Given the limited attention the previous literature has placed on the role of Vis in promoting tourism initiatives, this paper adopts an exploratory case study approach (Eisenhardt, 1989). The case under investigation is *Open to Meraviglia*, an Italian tourism promotion campaign launched by the Italian Ministry of Tourism and the Italian National Tourist Board (ENIT) in 2023. This case study is relevant for the aim of our research due specific reasons. First, 'Open to Meraviglia' leverage a virtual influencer in the context of tourism marketing - an area still unexplored; second, the campaign leverages Italy's historical heritage through a well-known figure (i.e., *Venere*) compared to VIs; third, has elicited significant negative sentiment among its audience. To answer our research questions, we employ a netnographic approach, enriching our qualitative analysis by engaging deeply in the digital interactions around *VenerItalia23* on Instagram. Netnography "as a marketing research technique, netnography uses the information that is publicly available in online forums to identify and understand the needs and decision influences of relevant online consumer groups" (Kozinets, 2002, p. 61). We chose a netnographic approach primarily due to its unobtrusive nature, allowing us to observe consumer behavior as our unit of analysis, rather than the person, in an environment unaffected by market research intervention (Kozinets, 2002). This method provides a transparent window into consumers' organic interactions, revealing the essence of their information-seeking behavior and the natural flow of word-of-mouth communication within online communities. In line with the approach proposed by Kozinets (2002), we followed these steps: 1) *entrée*; 2) data collection and analysis; 3) trustworthy interpretation. We began our investigation by formulating specific research questions aimed at understanding the negative responses to the *VenerItalia23* campaign. Identifying Instagram as the most relevant online forum for our study, we dedicated ourselves to thoroughly understanding this platform, the dynamics of the specific groups involved, and the individual participants contributing to the discussions. Next, we moved to the data analysis phase, firstly, we documented data from the computer-mediated communications of online community members, including the posts, comments, and interactions related to the *VenerItalia23* campaign on Instagram. Secondly, we recorded our observations concerning the community dynamics, member interactions, and the overarching meanings and sentiments being expressed. In line with Glaser and Strauss (1967), we collected data as long as new insights related to our research question emerged. The coding of the posts covered both data analysis and data interpretation (Spiggle, 1994), where each category later became a theme (Arnould and Wallendorf, 1994).

Case study: Open to Meraviglia. 'Open to Meraviglia' is an innovative tourism promotion campaign launched by the Italian Ministry of Tourism and ENIT, with the support of the Department for Information and Publishing of the Presidency of the Council of Ministers. This campaign represents a novel approach to marketing Italy's rich cultural heritage and diverse tourist offerings to the world, with Sandro Botticelli's *Venus* serving as its exceptional ambassador. At the heart of this initiative is the transformation of Botticelli's *Venus* into a modern virtual influencer, a figure that

personifies Italy's deep historical roots and modern appeal. This new Venus travels across Italy, from its iconic art cities to its quaint villages, promoting the country's breath-taking landscapes, culinary delights and vibrant array of tourist attractions. Designed by the Armando Testa Group, it unfolds through a multi-faceted strategy that includes a promotional video and a geographically diverse billboard campaign spotlighting the beauty of southern, central and northern Italy. As Venus travels through the different regions and municipalities participating in this digital campaign, new destinations, suggestions and itineraries will be unveiled, thereby enriching the storyline and inviting a worldwide community to discover Italy. The initiative is funded by a considerable investment from ENIT, which aims to reach key international markets through targeted promotional activities on multiple channels, including airport hubs, European railway stations with direct connections to Italy and digital ecosystems.

Results. From our analysis, the following three points emerge. We include some supporting comments that have been anonymized for privacy reasons.

1. Image quality and repetitiveness

The critique centers primarily on the low quality and repetitiveness of the imagery used in the campaign. The feedback ranges from disappointment to irony regarding the execution.

User 1: Ah well, it's really tiring to poorly cut out images from stock photo sites and have the captions translated by Google Translate, poor little Venus.

User 2: Oh, still rolling with stock photos, huh? Fantastic job there.

User 3: Venus, why the same face all the time? Your feed is a bit repetitive.

User 4: Photo taken with a 2005 cell phone with a 2-megapixel camera?

User 5: People who'd take better pics just by snapping them randomly.

These comments collectively illustrate a perception of the campaign as lacking in authenticity, creativity, and quality-key elements for engaging and inspiring potential tourists through a virtual influencer.

2. The lack of care, attention, and professionalism in a campaign worth 9 million euros

The second critical observation revolves around the perceived lack of meticulousness, attention to detail, and professionalism in a campaign that commands a substantial budget of 9 million euros.

User 6: So adding a location tag was too hard? Guess the 9 million euros couldn't cover that too, huh?

User 7: Besides the awful pics, I thought this page was all about getting tourists to Italy. Why are we even mentioning a tourism fair in Germany?

User 8: Just 4 random pics without even saying where they're at

User 9: Immerse yourself in medieval history," but Sutri was founded by the Etruscans, though

User 10: Anyway, no matter what you think, our Venus has 260K followers. I won't judge the content (though I'm tempted), but as an influencer, well, let's just say she's not exactly at the top of the popularity charts

The discourse surrounding the challenges encountered in a 9 million euro tourism campaign illuminates significant gaps in strategic planning and execution. The omission of geolocation tags, engagement with unrelated content such as a tourism fair in Germany, and the utilization of nondescript imagery are notable deficiencies. Moreover, the inaccuracies regarding the historical foundation of Sutri highlight a concerning oversight in content accuracy. Despite the virtual influencer Venus commanding a sizeable digital following, these missteps underscore a pivotal issue: the quantitative metrics of social media influence are insufficient substitutes for quality and relevance in content.

3. The quality of posts' description

The quality of the translation is another aspect that emerged from the analysis.

User 11: Seriously, who's doing your English translations? I've got a degree in language mediation and have been living in London for 13 years. If you need, I can help you out? For free, just for the love of our country.

User 12: Oh, it's really a hassle to badly crop out images from stock websites and have Google Translate do the captions, poor little Venus.

User 13: Your English has gotten better, finally you guys used ChatGPT like I suggested a while back.

User 14: Translating into English is tough, too.

User 15: A smooth translation, I would say...

The comments on the *VenerItalia* profile are full of irony, reflecting a critical yet humorous approach to the translation quality of the posts. From offers to help 'for the love of our country' to teasing remarks about relying on Google Translate and suggestions that improvements could be made by using ChatGPT, each comment is layered with irony.

Preliminary discussion and conclusion. These preliminary results represent a starting point as the research is still in progress. Yuan and Lou (2020) indicate that elements of source credibility significantly influence the parasocial relationships that develop between social media influencers and their followers. Our findings are linked to the four-dimensional definition of source credibility: attractiveness, similarity, expertise, and trustworthiness (Ohanian, 1990; Xie-Carson et al., 2023). Specifically, criticism has been directed at the repetitiveness and low quality of the images employed, noting that *VenerItalia23*, as a virtual influencer, lacks versatility in her expressions, rendering her presence static and unnatural. Our findings contradict prior research, which found faces of influencers in Instagram photos to

enhance engagement (Bakhshi et al., 2014; Jaakonmäki et al., 2017). Conversely, Xie-Carson and colleagues (2023) report that in the tourism context users prefer tourism images without the presence of the influencer.

Despite expectations that *VenererItalia23* might inspire followers to engage in similar experiences, mainly negative feedbacks are reported. Schiappa et al. (2007) explain that similarity involves the common traits that audiences share with media figures. The monotonous portrayal of *VenererItalia23*, particularly due to the repetitive expression in each post, might impede the audience's ability to connect with *VenererItalia23* as a genuine, authentic and persuasive character reflecting common values and interests. This observation detracts from the virtual influencers' attractiveness, a key driver of followers' mimetic behavior (Kim and Park, 2023). In terms of caption discourse, users even mock the caption, finding it to be quite impersonal.

Moreover, observations on the perceived lack of care and professionalism in this high-budget campaign reflect negatively on the perceived expertise behind *VenererItalia23*. In contrast to Liu and Lee's (2022) findings that users tend to absolve virtual influencers of responsibility for negative outcomes and instead direct their criticism at the creators or companies, in this case, our analysis suggests that users direct their criticism both at the VI itself and at the ENIT campaign. Furthermore, the feedback on the perceived negligence in campaign execution directly challenges her expertise. Expertise refers to the level of knowledge or skill in a specific field (Bargoni et al., 2024). In this case, the audience's perception is that the campaign lacks a deep understanding of effective tourism promotion. Specifically, they highlight that the campaign lacks thoroughness and attention to detail - high use of translation programs, little knowledge about historical backgrounds, and inappropriate content for promoting tourism. For instance, the presence of inaccuracies in posts that should be promoting Italian beauty, or the fact that the campaign aims to promote Italian tourism to an international audience, but then uses language that is not appropriate. The lack of expertise is closely linked to the perceived trustworthiness of the audience. Trustworthiness (Wiedmann and von Mettenheim, 2020) pertains to the honesty, genuineness, and truthfulness of the source. Issues such as the use of inadequate translations, lack of geographical tagging, and inaccuracies in historical information not only reflect a disregard for detail but also reduce the perceived trustworthiness of the information in the post.

Our findings highlight the importance of considering three main attributes that users may influence consumers' reactions to any post: source, image composition, and caption discourse.

Conclusion and research limitations. We provide some insights for embedding VIs in tourism promotion. Specifically, our investigation examines the Italian 'Open to Meraviglia' campaign, with the aim to unveil the motivation underlying negative user comments. Although the potential of VIs to open new marketing opportunities with their flexibility and control, this case study reports a high number of critiques.

Grounded on the source credibility model (Ohanian, 1990), we found that *VenererItalia23* as a VIs ambassador in charge of promoting Italian tourism abroad, is failing to engage the public positively. The criticisms leveled at *VenererItalia23* - from the repetitive and poor quality of the pictures to the impersonal nature of the captions - highlight a failure to harness the distinctive capabilities of VIs and to create a genuine, intimate connection with the audience. Specifically, we report that her lack of expressive versatility, low-quality image, and impersonal caption discourse reduce her attractiveness, similarity, expertise and trustworthiness. In particular, the low level of attention to detail and professionalism in terms of accuracy of content and use of language suggests a significant underestimation of the audience's expectations of authenticity and expertise in storytelling. At first glance, users prefer authentic and engaging storytelling, high-quality images and potentially without the intermediary of a virtual influencer. Virtual influencers, like *VenererItalia23*, should be considered not only as marketing tools but as storytellers who embody the essence of the destination they represent. Moreover, our findings do not exclusively ascribe the negative feedback to the digital nature of *VenererItalia23* as a virtual influencer, potentially distinguished from a genuine, real influencer. They instead highlight the initiative to resurrect the essence of Botticelli's *Venus*, thereby indicating that the primary intent is not to persuade the audience of its authenticity as a real-life influencer embodying human-like physicality and behaviors. Despite this, our analysis suggests that introducing variability in expressions to foster an element of surprise for the audience could be more advantageous. Such an approach may mitigate the audience's habituation to an unchanging expression.

The limitations of this study lie primarily in its exploratory nature and methodological approach. Furthermore, the analysis is limited to a singular campaign and its acceptance among Instagram users, which may not entirely reflect the multiple ways VIs influence tourism marketing in different cultural contexts, platforms and audiences. Also, sentiment and thematic analysis can be opened up to interpretation by the researcher, which introduces a degree of inherent subjectivity into the findings. A larger sample of Instagram accounts of VIs specifically designed to promote tourism and chosen as symbols, rather than any virtual influencer, should be used to replicate this research to validate and generalize the preliminary results.

Managerial implications. When interpreting these findings to offer some managerial implications, it is important to note that they are in a preliminary stage. Drawing on these preliminary findings, we argue that tourism managers should clearly communicate the role of the VI and the fictional nature to meet and manage users' expectations. Specifically, they should be transparent on the role of the VI, by explaining the creative choices behind the choice to leverage a historical figure and clarify that a VI serve as a storytelling tool rather than a "traditional" influencer. Furthermore, they should invest in high-quality imagery, ensuring different and expressive content, and avoiding repetitive faces of VI on the posts that can lead to user disengagement. For instance, a video of *Venus* tasting local Italian cuisine or participating in traditional events can make the content more engaging and relatable. Moreover, managers may encourage followers to share their own experiences with the campaign's featured destinations and tag the VI. Highlighting user-generated content on the VI's profile can increase her authenticity and create a supportive community. For example, followers could

be invited to share their photos of destinations that were previously posted by VenereItalia23, and she could then “react” or “comment” the posts. Furthermore, to avoid monotony in facial expressions, managers could leverage animation software to create smiles, winks, and other emotive gestures that humanize the VI, and enhance Vi’s expressive face. Importantly, the congruity between the facial expression and the emotional tone of the post should be considered. For instance, for a joyful landscape, a look of awe could be implemented. From a content perspective, agencies and managers leveraging VI as tourism brand ambassadors could collaborate with historians, artists, chefs, and other local experts to ensure authenticity and accuracy in the posts. We would therefore recommend posting narratives that capture the audience’s interest, using a mix of historical facts, cultural curiosities, and personal stories

Originality of the paper. This research, though at its preliminary stage, presents elements of originality in the investigated topic. The originality of this paper lies in its exploration of virtual influencers (VIs) within tourism marketing, particularly focusing on their influence and reception in promoting national tourism through social media campaigns. Specifically, this study leverages the ‘Open to Meraviglia’ campaign, initiated by the Italian Ministry of Tourism, which employed Botticelli’s Venus as a VI to enhance Italian tourism globally. This approach of utilizing a historically significant figure as a VI, specifically designed to promote the essence of a nation’s heritage, sets a novel precedent in the field. Furthermore, our analysis examines the underlying motives of mixed reactions from the audience, especially the negative ones in the tourism context - a still little investigated area. In addition, by highlighting the specific challenges of the use of a cultural icon as a VI in tourism marketing, our preliminary findings contribute to the academic discourse on digital marketing and influencer campaigns, aiming to provide insights that could be applicable beyond the Italian context to the global use of VIs in promoting tourism.

Mitigating the Negative Effects of Human-like Virtual Medical Agents on Patients' Emotions. Results From a Preliminary Experimental Study

ANDREA SESTINO¹ ALFREDO D'ANGELO² RUSSELL W. BELK³

Abstract

Virtual agents captured greater attention in various sectors, including healthcare, with potential applications such as chatbots and avatars of medical professionals, to assist final patients and boost their journey. However, understanding their impact on patients' reactions remains a still hazy, critical area of investigation. Drawing upon the Uncanny Valley Theory, through an experimental study, this paper examines how patients react to the human-like similarity (low vs. high) of medical doctors' avatars, in digital healthcare platforms. Results reveal that higher human-like similarity led to higher negative emotions, because of the effect of both perceived anthropomorphism, and creepiness. Nonetheless, the negative impact is attenuated by individuals' digital literacy, suggesting that familiarity with digital technologies – and investing in policies aimed to allow final users to “sage” the benefits derivable from new technologies – may mitigate adverse emotional responses, thereby facilitating the acceptance of such digital interventions in healthcare.

Keywords: virtual agents; medical; healthcare; anthropomorphism; creepiness; digital literacy; negative emotion

Framing of the research. Immersive technologies, including VR, AR, and MR, empowered by AI, are reshaping business propositions across various sectors such as education, entertainment, tourism, and healthcare (Wang et al., 2019). Avatars, as integral components of immersive experiences, facilitate interactions between individuals and virtual environments, particularly in healthcare settings (Miller & Polson, 2019; Sestino & D'Angelo, 2023). They serve as interfaces for teleconsultations, healthcare chatbots, and therapy applications, improving patient care and communication (see Winkler et al., 2023 for a review). However, the design of avatars must carefully balance realism and likability to avoid triggering negative responses, as explained by the Uncanny Valley theory (Kätsyri et al., 2015; Mori, 1970). Digital literacy, defined as individuals' competence in understanding and critically evaluating digital technologies, influences perceptions of virtual worlds, including in healthcare (Merchant, 2009; Kamal et al., 2020). Higher levels of conscientiousness and education correlate with more positive attitudes toward new technologies (Sunny et al., 2019). Digital literacy acts as a moderator, mitigating negative perceptions of new technologies and empowering individuals to engage responsibly (Ahmed & Rasheed, 2020; Bao & Lee, 2023). The Uncanny Valley theory is significant in avatar design, emphasizing the need to balance human-likeness to avoid negative emotional responses (Berger et al., 2018; MacDorman & Ishiguro, 2006). Based on such assumptions, anthropomorphism and creepiness may the relationship between avatar human-likeness and negative emotions (Epley et al., 2007; Mouri et al., 2012; Raff et al., 2024). Anthropomorphism enhances engagement but may lead to discomfort if avatars become too human-like, while perceived creepiness arises from incongruity between human-like appearance and behavior (Epley et al., 2007; Koschate et al., 2006; Raff et al., 2024). Digital literacy moderates these effects, helping individuals navigate technology complexities (Black & Steinkuehler, 2009; Roberts et al., 2023).

Purpose of the paper. This study delves into the impact of human-like similarity in the healthcare sector on individuals' negative emotional responses. It explores how perceived anthropomorphism and creepiness mediate this impact. Anthropomorphism, the attribution of human traits to non-human entities, and perceived creepiness are investigated as potential mediators between human-like similarity and emotional reactions (Epley et al., 2007; Koike & Loughnan, 2021). Perceived creepiness, referring to discomfort or unease, particularly in the uncanny valley of healthcare avatars, is also considered (Mouri et al., 2012; Raff et al., 2024). Through an exploratory research design, an experiment was conducted with 206 international participants, revealing that higher levels of human-like similarity positively influence negative emotions, mediated by perceived anthropomorphism and creepiness. Notably, this relationship is negatively moderated by individuals' digital literacy, which helps mitigate negative reactions. By

³ e-mail: rbelk@schulichyorku.ca

unraveling these complex dynamics, this research aims to offer insights into designing healthcare avatars for better and more user-friendly virtual healthcare experiences.

Methodology. The methodology comprised a pre-test to verify the efficacy of stimuli designed to manipulate human-like similarity in avatars. Using different avatars, one human-like and the other cartoon-like, participants rated the human likeness. Results showed higher ratings for the human-like avatar, confirming the manipulation's effectiveness.

In the main study, a questionnaire was administered to assess reactions to different avatar types in digital healthcare services. Participants were assured of data anonymity and were asked to evaluate their digital literacy. They were then randomly assigned to either low or high human-like similarity conditions, interacting with a medical doctor's avatar. Reactions were measured in terms of negative emotions, perceived creepiness, and anthropomorphism. Based on our between-subjects experimental research design, the two-cell experiment has been built on two different conditions related to the two different type human-like similar avatar (low vs. high), pre-tested in the previous study.

The questionnaire was comprised three main sections. In the introduction section, participants were welcomed with a reassurance regarding the anonymity of their responses and the meticulous handling of data. It was explicitly communicated that all data would be utilized solely in an aggregated manner, aligning with rigorous scientific purposes, aimed at alleviating any apprehensions among the participants (Podsakoff et al., 2019).

At the end of this section, we asked participants to self-evaluate their Digital literacy by using items drawn by considering both the digital skills required by the "DigiComp" Framework as a tool proposed by the European Union to measure individuals' digital skills. We also utilized Reddy and colleagues' (2023) recommended self-perception measure (i.e., "Please self-rate your digital culture, and your ability to critically evaluate the reliability and credibility of information found online, considering factors such as source credibility, bias, and relevance"; $\alpha = .922$). The answer was assessed on seven-point Likert scales (1 = "Low proficiency", and 7 = "High proficiency").

In the second section of the questionnaire, participants were randomly assigned to one of two different conditions (low vs. high human-like similarity), with a medical doctor's avatar. Then, in the third section, we asked for participants' reactions in terms of negative emotions based on the scale related to the negative emotional display response drawn by Du and colleagues (2011), (e.g., "I think that the doctor's avatar looks down on me in an aloof way", "I think that the avatar frowns at me and looks clearly impatient", and so on; $\alpha = .964$), on the basis of prior studies evaluating uncanny valley assumptions, emotional responses, and psychophysiological reactions (e.g., Ratajczyk et al., 2019). The perceived creepiness measure used a scale suggested by Raff et colleagues (2024) (e.g., "This doctor's avatar would be comparable to an invisible guest in my home", "This doctor's avatar reminds me of the evil", and so on; $\alpha = .778$); and their anthropomorphism was measured using McLean and colleagues' (2019) scale (e.g., "When I communicate with the doctor's avatar, it feels like someone is near me", "The interaction experience with the doctor's avatar, is close to that with a human being", and so on; $\alpha = .957$). Finally, in the fourth section we asked for their basic sociodemographic data. Both perceived creepiness and anthropomorphism, together with participants' negative emotions, were assessed on a seven-point Likert scales (1 = "Completely disagree", and 7 = "Completely agree").

Results. Based on our research design, in this study we utilized moderated mediation analysis to investigate the effects of human-like similarity of avatars on individuals' negative emotions, mediated by perceived anthropomorphism and perceived creepiness, with digital literacy moderating these relationships. SPSS Model 87 was employed for analysis (Hayes, 2015). Results indicated a significant direct effect of high human-like similarity on negative emotions. Mediation analysis revealed that high human-like similarity led to increased anthropomorphism, which in turn increased perceived creepiness. The serial mediation effect of human-like similarity on negative emotions via anthropomorphism and perceived creepiness was significant. Furthermore, digital literacy moderated these relationships. Individuals with lower digital literacy exhibited intensified negative reactions to highly anthropomorphic avatars, consistent with the Uncanny Valley theory. Conversely, individuals with higher digital literacy demonstrated reduced susceptibility to the adverse emotional impact of anthropomorphic avatars, indicating a nuanced understanding of the artificial nature of avatars and mitigated perceived creepiness. This effect extended beyond technical proficiency, reflecting a heightened digital consciousness. Overall, the study supported the hypothesis that high human-like similarity in avatars increases negative emotions, mediated by anthropomorphism and perceived creepiness, with digital literacy playing a crucial role in mitigating adverse emotional reactions.

Research limitations. Despite the research findings, some issues may persist in calibrating the relationship between avatar human likeness and negative emotions due to various contributing factors such as virtual environments and individual differences in personality traits and cultural backgrounds. Future studies should aim to integrate these findings into technology adoption models to further illuminate perceptions of doctor virtual agents and their anthropomorphic characteristics.

Managerial implications. Based on the findings of the research demonstrating that higher human-like similarity of doctors' virtual agents leads to increased perceived anthropomorphism and creepiness, resulting in negative emotions, with a mitigating effect observed among patients with higher digital literacy, the following managerial implications can be drawn for marketers and managers. Managers. Firstly, healthcare managers should consider tailoring the design of virtual agents to strike a balance between human-like features and technological aspects. While incorporating human-like characteristics may enhance perceived anthropomorphism, it's crucial to avoid excessive resemblance to humans to prevent feelings of creepiness among patients. This necessitates collaboration between healthcare professionals and technology experts to design virtual agents that are perceived positively by patients. Secondly, by recognizing the mitigating effect of digital literacy on the negative emotional response to highly anthropomorphic virtual agents, healthcare managers should prioritize initiatives aimed at enhancing patients' digital literacy. Implementing educational

programs and resources focused on digital literacy can empower patients to better understand and interact with virtual agents, thereby reducing the likelihood of experiencing negative emotions and increasing acceptance of technological advancements in healthcare settings. Moreover, healthcare managers should provide comprehensive training and support to healthcare staff involved in the implementation and utilization of virtual agents. This includes educating staff members on the potential impact of virtual agent design on patient perceptions and emotions, as well as equipping them with strategies to effectively communicate the benefits of digital technology to patients. By fostering a culture of digital literacy within healthcare organizations, staff members can play a pivotal role in facilitating patients' acceptance of technological innovations. In conclusion, healthcare managers must recognize the importance of striking a balance between human-like features and technological functionality in virtual agent design, while also prioritizing initiatives to boost patients' digital literacy. By proactively addressing these factors, healthcare organizations can foster a culture of acceptance and appreciation for technological advancements in healthcare delivery, ultimately improving patient outcomes and satisfaction.

Originality of the paper. The exploration of the relationship between human-like attributes in virtual agents employed by healthcare professionals and patient perceptions constitutes a novel avenue of inquiry within research studies. This paper unveils a significant finding wherein heightened similarity between doctors' virtual agents and humans correlates with amplified perceptions of anthropomorphism and creepiness among patients, consequently engendering negative emotional responses. Notably, this study contributes to existing literature by elucidating that such effects are mitigated among patients exhibiting greater levels of digital literacy. This insight is particularly noteworthy as it not only enriches our understanding of human-computer interaction but also intersects with the Uncanny Valley theory, providing empirical support for its applicability within the context of healthcare technology. Thus, this research not only contributes original findings but also underscores the importance of considering individual differences in digital literacy when designing and implementing virtual agents in healthcare settings.

Scaling Consumer Neuroscience Technologies for Individual and Societal Well-Being. A Bibliometric Analysis of Precursors

ANDREA BAZZANI¹ GIORGIO MANFRONI² UGO FARAGUNA³ GIUSEPPE TURCHETTI⁴

Contributors statement:

AB and GM conceptualized the work and conducted the bibliometric analysis. AB drafted the extended abstract. GM created the graphs related to the bibliometric analysis. UF and GT contributed to the work's conceptualization, provided the necessary resources to conduct the study, and reviewed the work.

Abstract

In this work-in-progress research, we conducted a bibliometric analysis on the integration of consumer neuroscience technologies and wearable devices from the biomedical sector into studies of individual well-being. With rising consumer awareness for health monitoring, facilitated by consumer-grade devices that measure physiological parameters, there is an expanding interest in using these technologies also for marketing and consumer behavior research. This shift marks a significant development in consumer neuroscience, a field evolving to incorporate a broader range of physiological parameters through wearable technology. Such advancements raise important questions about the feasibility of gathering detailed data in everyday settings. Addressing the utilization of neurophysiological data to examine consumer behavior necessitates understanding the challenges consumers face when adopting these technologies, including ethical concerns. Our initial investigation focuses on concrete barriers to adoption, particularly concerning device usability and scalability, framed within the Technology Acceptance Model.

The ultimate goal of our research project is to investigate progress in collecting neurophysiological data from consumers and their willingness to share this information for diverse purposes, such as marketing research. Given the novelty of this area and the need for empirical data to fully understand consumer reactions to technology use, this ongoing work represents an initial step. We conducted a bibliometric analysis of existing literature from the Scopus database to evaluate the current state of research and suggest future research directions. This analysis, drawing from literature between 2009 and 2024, employs VOSviewer and Biblioshiny to examine publication trends, citation networks, and thematic developments.

Findings indicate a growing interest from 2011 until just before 2023 in employing neurophysiological tools for health monitoring and improving well-being, with a notable shift towards AI-driven research methods like machine learning and deep learning in recent years. There is a continuous emphasis on analyzing health metrics, such as heart rate variability, to assess well-being and stress levels. The geographical analysis identifies the United States, the United Kingdom, China, and Italy as key contributors to this research area. Keyword co-occurrence analysis uncovers clusters focused on psycho-physiological state monitoring, the usability of technology, behavior modification interventions, public health applications, and the integration of AI with wearable technology.

This study highlights the transformative potential of wearable neurophysiological devices in consumer behavior research, underscoring the importance of cross-disciplinary collaboration to establish standardized research methodologies. Managerial implications emphasize the significance of understanding consumers' comfort and data-sharing willingness to integrate these technologies into daily life, thus enhancing consumers' well-being. This paper's originality lies in mapping out a research and application roadmap for the marketing and well-being sectors, suggesting how leveraging marketing approaches can also improve individual and societal well-being.

Keywords: consumer neuroscience, precision business, consumer well-being, wearable technology, technology acceptance model.

Framing of the research. Consumers are becoming increasingly mindful of their well-being, a trend bolstered by the widespread availability of consumer-grade devices that can quantify physiological parameters (e.g., Tikkanen et al., 2023; Fuentes and Sörum, 2019).

This technological advancement enables the objective measurement of aspects that would otherwise remain subjective, marking a significant shift in how individuals engage with their health and wellness during daily activities. This trend has sparked a growing interest in leveraging unconventional data sources also for marketing purposes (e.g., Ferreira et al., 2021). Wearable devices have not only gained a significant market presence but have also introduced new paradigms for advancing consumer behavior research.

The potential to accurately and objectively understand consumer behavior and customize products and services to enhance consumer satisfaction and well-being has its roots in the nascent field of consumer neuroscience (Plassmann and Karmarkar, 2019). This field is now expanding to include the collection of additional physiological parameters through wearable technology (Clithero et al., 2024). The emergence of this interest within marketing literature highlights crucial questions about the practicality of collecting such detailed data in everyday, natural settings.

Recognizing the utility of using (neuro-)physiological data to investigate consumer behavior requires an exploration of the barriers to technology adoption firstly faced by consumers, including ethical concerns (e.g., Wardlaw et al., 2011; Dobson et al., 2023).

Our preliminary work examines tangible adoption barriers, particularly those related to device usability and scalability, within the framework of the Technology Acceptance Model (TAM) (Davis, 1989). TAM posits that the decision to adopt technology is significantly influenced by an individual's perceptions of its usefulness and ease of use. These factors shape attitudes toward technology use, influencing behavioral intentions and ultimately leading to technology adoption. It is evident that social and cognitive aspects also play roles in technology adoption decisions.

Our research aims to explore advancements in the collection of consumers (neuro-)physiological data and consumers' willingness to share such information for various purposes, including marketing research. Using TAM as our guide, we intend to investigate how enhancing usability perceptions of devices collecting (neuro-)physiological data could positively affect the acceptance of such technologies from both consumers' and companies' perspectives.

Given the field's infancy and the need for empirical data to fully understand consumer responses to technology integration, the initial contribution of our work-in-progress research is a bibliometric analysis of existing literature. This analysis aims to assess the current state of research and propose directions for future theoretical and empirical studies. Insights from this analysis could also help businesses refine their marketing strategies to better match consumer preferences.

Our objective is to map the current research landscape at the intersection of various disciplines and explore potential applications of wearable technology in consumer behavior research. Furthermore, we aspire to lay the foundation for a comprehensive literature review, seeking to reveal practical implications for academics, marketing professionals, and healthcare providers. For healthcare providers, integrating health-related data from wearable devices into their systems offers a new perspective on health prevention (e.g., Lu et al., 2020; Bayoumy et al., 2021).

This holistic approach is crucial for understanding how this promising area can advance consumer research, particularly in leveraging marketing to enhance individual and societal well-being.

Methodology. To conduct a comprehensive and up-to-date analysis of the literature on the scalability and application of consumer (neuro-)physiological technologies for consumer behavior and well-being, our research adopted a bibliometric approach. This method allowed us to quantify and explore patterns in the existing body of work within this emerging interdisciplinary field.

Data Collection

The initial phase involved conducting a systematic search within the Scopus database, employing a set of keywords relevant to consumer neuroscience techniques and wearable devices aimed at monitoring consumer health and enhancing well-being. These keywords, which spanned both techniques and conceptual frameworks, included "Electroencephalography," "Eye-Tracking Technology," "Heart Rate Monitoring," "Wearable Technology," "Usability," and "Well-Being." We crafted our search query using these keywords connected by Boolean operators, focusing on titles and abstracts to capture relevant studies comprehensively.

We limited our search to original works and reviews published in English, excluding book chapters, conference papers, and similar publications to maintain a focus on peer-reviewed journal articles. This process led to the identification and analysis of 242 articles.

Bibliometric Analysis

For the bibliometric analysis, we employed two primary tools: VOSviewer and Biblioshiny.

VOSviewer (www.vosviewer.com) was crucial for exploring the co-occurrence networks of key terms within the literature (van Eck and Waltman, 2011), facilitating the visualization of relationships between terms. The proximity

between two items on the map indicated the strength of their association within the literature, enabling us to identify clusters of related terms and reveal the main thematic focuses within the field (van Eck and Waltman, 2010).

Biblioshiny, a web interface for the *Bibliometrix* R package, offered an accessible platform for our bibliometric analysis (Aria and Cuccurullo, 2017). It allowed for the importation, cleaning, and analysis of bibliographic data, generating interactive visualizations and network diagrams that were instrumental in deciphering the landscape of scalable (neuro-)physiological technologies for consumer research. The tool's comprehensive analysis capabilities enriched our study with insights into publication trends, authorship patterns, and geographical research distribution.

Results. Our findings are presented in three distinct sections. The first section details the temporal evolution of publications, including the annual number of publications (Figure 1) and the changing frequency of keywords over time (Figure 2). The second section examines the geographic distribution of research activities, showcasing the locations of corresponding authors, publication counts by country (Figure 3), citation rates (Figure 4), and international collaborations (Figure 5). The final section delves into keyword network analysis and the evolution of topic networks over time (Figures 6 and 7).

Temporal Evolution of Research

Our dataset reveals an overall increase in annual publication volume up to the year 2023, indicating a growing interest in scalable neurophysiological techniques for consumer well-being (Figure 1). This surge in research activity, notable from 2011, reaches its peak just before 2023.

Figure 1 – Annual Scientific Production

Figure 2 presents a detailed visualization of the evolution of research interests, illustrating the frequency of key terms associated with this area of study from the early 2000s to 2023. Utilizing a horizontal bar graph enhanced with bubbles of varying sizes, the graph displays the yearly frequency of each term. Here, the size of each bubble is directly proportional to the term's prevalence in that year, with larger bubbles indicating a greater frequency.

In recent years, terms related to Artificial Intelligence (AI) use, such as "machine learning" and "deep learning," have become predominant, signaling a significant pivot towards computational and AI-driven research. Concurrently, terms like "electroencephalography" and "heart rate" have maintained their prominence, reflecting a growing interest in these topics over the last few years. Similarly, an emphasis on "wearable technology" likely reflects the era's technological advances and their application in enhancing human health and behavioral studies.

The graph also revisits the early to mid-2000s, highlighting a marked shift from "patient satisfaction" to broader terms such as "quality of life," and even focusing on specific aspects like psychological well-being, as presumably indicated by the high frequency of the term "anxiety."

Interestingly, after 2010, there is a noticeable increase in the frequency of a variety of keywords, including significant mentions of "human" and the gender-specific terms "female" and "male." This trend may signify either an increased focus on gender-specific research or a growing recognition of the importance of including sex-disaggregated data in scientific studies.

Furthermore, the emergence of terms like "telemedicine" and "health behavior" in the more recent parts of the graph underscores the growing interplay between technological innovation and healthcare practices, along with an increased focus on the behavioral dimensions of health.

Notably, the term "patient compliance" appears early in the timeline but consistently shows a lower frequency over the years, suggesting its role as a more specialized topic within the broader research domain. This progression not only reflects shifts in technological advancements and potential societal changes but also highlights the emergence of scientific interdisciplinary focuses.

Figure 2 – Trend Topics

Geographic Distribution of Research Activities Worldwide

The following figures (Figure 3 and Figure 4) provide an insightful overview of the production of scientific literature across various countries. This distribution is distinguished by publications originating from a single country (SCP, depicted in cyan) and those resulting from international collaborations, known as multiple country publications (MCP, depicted in red). The United States leads in scientific output, boasting the highest total count of scientific works. It is closely followed by the United Kingdom and China, highlighting their significant contributions to the global research landscape.

Notably, countries like the United Kingdom, China, and the Netherlands, which show a predominance of red in their distribution, demonstrate a strong inclination towards international collaboration. In contrast, countries with a higher proportion of cyan, such as the USA and Canada, tend to produce more domestically-authored publications.

Italy ranks fourth in terms of document production, displaying a balance between SCP and MCP. Following Italy, Canada and Switzerland exhibit a lower total document output compared to the leading countries but still play vital roles in the global scientific community.

Figure 3 – Scientific Collaboration across Different Countries

Figure 4 ranks countries according to the number of citations their scientific publications in this research area have received. In this visualization, each country is represented by a dot positioned along the horizontal axis, corresponding to the total number of citations that country's research outputs have garnered. From this visualization, it is clear that the United States is the undisputed leader in terms of citations, significantly outdistancing its closest competitors, the United Kingdom, China, Italy, and France. Following France, countries such as Australia, Egypt, Switzerland, Canada, and Belgium are notable for their closely clustered citation counts.

Figure 4 – Number of Citations by Country

Finally, the "Country Collaboration Map" (Figure 5) provides an informative, albeit intricate, depiction of the network of partnerships between countries. The thickness of each line directly correlates with the volume of research collaborations between two countries. The predominant presence of the United States is immediately evident, with a strong network that spans diverse geographical regions, showcasing an extensive engagement in global scientific endeavors. In contrast, the collaborative efforts of Canadian research institutions are highlighted, showing a strong orientation towards Europe. European collaboration, in turn, is represented as a tightly-knit network, underscoring the rich tapestry of inter-country research relationships within the continent. These connections not only strengthen Europe's internal scientific discourse but also project outward, demonstrating a commitment to global scientific collaboration.

Figure 5 – Countries Collaboration Map

Country Collaboration Map

Co-occurrence Analysis of Keywords

We performed a co-occurrence analysis using VOSviewer on authors keywords. By selecting the top 30 keywords that exceeded the co-occurrence threshold set at two times, we generated Figure 6 with a resolution of 20 and a minimum cluster size of 10. As a result, we identified five distinct clusters, each represented by different colors.

The first cluster, shown in red, appears to focus on the monitoring of psycho-physiological states. This cluster includes keywords such as "heart rate variability," "autonomic nervous system," and "biomarkers," along with "stress detection," "anxiety," and "mental stress." Consistent with the "Trend Topics" graph (Figure 2), we observe a growing interest in keywords related to "mental health," a vital dimension in assessing individual well-being. Notably, biomarkers and physiological parameters used to measure stress and related phenomena are linked to the activity of the autonomic nervous system (ANS). ANS is responsible for the regulation of many physiological and involuntary functions, such as heart rate. ANS is divided into two different systems, i.e., the sympathetic nervous system and the parasympathetic nervous systems, which regulate the "fight or flight" response, and the "rest and digest" activities, respectively. These systems collaborate to maintain bodily equilibrium and respond to stress (McCorry, 2007). Heart rate variability (HRV) has attracted increasing attention as an indicator of ANS activity. A higher HRV indicates better cardiovascular fitness, stress resilience, and overall health, while a lower HRV suggests stress, fatigue, and possibly underlying health issues (Shaffer and Ginsberg, 2017). HRV is applied in various fields, including consumer research, to evaluate autonomic nervous

system function and overall well-being. The red cluster also notably includes keywords related to techniques commonly applied in neurophysiology, including "actigraphy" and "electroencephalography" (EEG), which are commonly applied, for instance, in the study of sleep and circadian rhythms. With respect to these keywords, we observe a partial overlap between the red cluster and the green cluster.

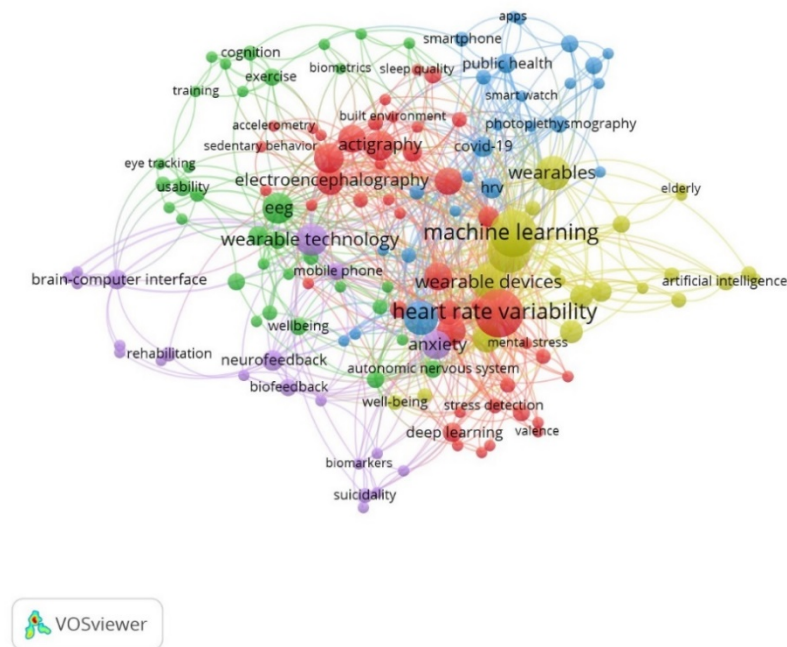

The **green cluster** primarily contains technology-related keywords, such as "wearable technology," "EEG," and "eye-tracking." Among consumer neuroscience techniques, EEG and eye-tracking are two of the most used tools. This cluster could indicate a focus on the usability of these techniques for collecting (neuro-)physiological data, and their application to human "cognition," "training," and "well-being."

The **purple cluster** emphasizes some of the possible direct applications of collected information through neurophysiological devices in order to modify individual behavior. We, indeed, notice keywords like "neurofeedback" and "biofeedback." Neurofeedback and biofeedback are methods that train individuals to enhance their health and performance by providing real-time feedback on physiological functions (Yu et al., 2018; Marzbani et al., 2016). Biofeedback offers insights into bodily functions like heart rate and muscle tension, supporting stress management and the treatment of hypertension and chronic pain. Neurofeedback specifically targets brain activity, aiding individuals in modifying their brain waves to improve cognitive performance and treat conditions such as ADHD and anxiety. Both techniques exploit the mind-body connection to foster self-regulation and awareness for better well-being.

The **blue cluster** highlights a broader potential application of these technologies, extending beyond individual assessment and intervention. Keywords like "smartphone," "public health," "apps," "smartwatch," and "COVID-19" emphasize the use of mobile technology in public health, particularly in response to the pandemic (Budd et al., 2020), indicating an interest in leveraging wearable technologies, smartphones, and apps for health monitoring and disease tracking (e.g., Lu et al, 2020; Bayoumy et al., 2021).

Finally, the **yellow cluster** focuses on keywords related to the integration of Artificial Intelligence with wearable technology. The occurrence of keywords such as "machine learning", "deep learning", and "artificial intelligence" can indicate a strong emphasis in recent years on the computational and algorithmic aspects of data analysis and the development of intelligent systems in the wearable technology context.

Figure 6. The Co-Occurrence Network of the Top 30 Keywords Analysed.

Lastly, **Figure 7** displays the same findings as Figure 6, providing a snapshot of the scientific landscape and its evolution over the timespan of the last few years (2019-2023).

Figure 7. The Co-Occurrence Network of the Top 30 Keywords Analysed Over Time.

Discussion. The objective of this work-in-progress research was to map the current research landscape at the intersection of various disciplines and explore potential applications of wearable technology in consumer behavior research.

For this purpose, we conducted a bibliometric analysis to assess the current state of research.

Our initial bibliometric analysis has unveiled key insights that can provide a solid groundwork for discussing the development and barriers to adoption of (neuro-)physiological technologies in consumer behavior research. Our data reveals a noticeable upward trend in scholarly publications on this interdisciplinary topic since 2011, with a peak occurring just before 2023. This trend highlights a burgeoning academic interest in the applicability and scalability of (neuro-)physiological tools for monitoring individual health and enhancing well-being, which is central to our investigation within the Technology Acceptance Model (TAM) framework (Davis, 1989). Notably, recent years have witnessed a shift towards AI-driven research in this domain, with “machine learning” and “deep learning” emerging as prominent terms. This shift could emphasize the growing importance of computational methods in improving technology implementation.

Furthermore, our analysis has consistently shown an interest in monitoring health-related metrics, such as heart rate variability, which can be applied to evaluate overall well-being/stress, also in consumer behavior research (Kakaria et al., 2023).

In a geographical perspective, our findings highlight that the leading contributors in terms of publication output and citation impact are the United States, the United Kingdom, China, and Italy, with different levels of international collaboration.

The co-occurrence analysis of author keywords paints a complex research landscape, identifying five different clusters. We distinguished a cluster mainly focused on monitoring psycho-physiological states (e.g., stress vs well-being); a second cluster containing keywords related to technology usability; a third cluster referring to behavior modification through “neurofeedback” and “biofeedback”; a fourth cluster suggesting public health applications; and a fifth cluster reporting keywords linked to the integration of artificial intelligence with wearable technology. Particularly, AI-driven systems can enhance computational capabilities for data analysis and could provide platforms that may interactively assist consumers in understanding the neurophysiological data collected through wearables, and potentially in adjusting their behaviors accordingly.

Standing at the intersection of multiple disciplines, our analysis highlights the promising applications of wearable technology in consumer behavior research, underscoring its potential to transform this field.

Limitations and Future Research Agenda. We acknowledge the descriptive nature of our ongoing work on the potential applications of consumer neuroscience and wearable technologies for enhancing consumer well-being. Opting for a bibliometric analysis has been pivotal in shedding light on the foundational aspects of this emerging, interdisciplinary field. Although recent academic efforts have made topics related to consumer neuroscience technologies more visible (e.g. Bazzani et al., 2020), they often fail to adequately explore the complex interactions between various technologies that collect physiological data and their applications in marketing (e.g., Clithero et al., 2024). We admit that our study has limitations, notably its inability to exclusively focus on scientific contributions that directly explore the

integration of scalable consumer neuroscience technologies within the marketing research landscape (e.g., Alvino et al., 2020).

Therefore, more research is needed. However, through this preliminary study, we intend to underscore the importance of disciplines that contribute to developing user-friendly devices capable of collecting (neuro-)physiological parameters for consumer behavior research. Recognizing the benefits of interdisciplinary collaboration among neuroscience, medicine, and bioengineering professionals is a crucial step forward. This collaboration would ideally lead to the creation of a standardized research protocol for applying scalable versions of such techniques in marketing experiments.

Moreover, we acknowledge the limitations imposed by organizing keywords into five distinct, somewhat arbitrary categories. As a next step, conducting a systematic literature review is essential to establish structured guidelines for both scholars and practitioners.

Managerial implications. The adoption of wearable consumer-grade devices that capture (neuro-)physiological data has significant implications for marketing scholars and professionals, as well as for healthcare providers. Current research is focused on empirically demonstrating how these technologies can be integrated into consumer daily lives to enhance health outcomes and well-being (e.g., Lu et al, 2020; Bayoumy et al., 2021). A key consideration is understanding when consumers are comfortable relying on these devices for accurate physiological monitoring to improve well-being and for what purposes they are willing to share their data. According to the Technology Acceptance Model (TAM), improvements in usability and perceived usefulness are essential for the broader adoption of wearable (neuro-)physiological devices in everyday consumer life. A positive user experience can increase satisfaction and lead to word-of-mouth recommendations, accelerating market adoption. Manufacturers and marketers should prioritize designing intuitive interfaces and effectively communicate the tangible benefits of their devices.

For businesses, the data gathered from these devices could provide useful insights beyond traditional survey methods, offering a deeper understanding of consumer behavior, including activity peaks and mood fluctuations. These insights are invaluable for crafting tailored marketing strategies and product offerings. For instance, fitness brands could offer incentives for sharing health data to gain insights for customized product development. Health insurers that encourage healthy living through wearable devices can also use the collected data to customize their services (e.g., Nayak et al., 2019). Applying these strategies to industries like hospitality can improve customer experiences, enhancing satisfaction and loyalty (Kansakar et al., 2019).

Moreover, policymakers can use neurophysiological data collected through wearables to identify vulnerable populations, and modify communication strategies accordingly, to better reach them. This would increase the impact and relevance of institutional communication during emergencies, as well as the effectiveness of public health messages. Specifically, healthcare providers stand to benefit from this data by targeting services to patients and employing this knowledge to increase the effectiveness of public initiatives for health prevention.

Originality of the paper. We conducted a bibliometric analysis to explore the development of consumer neuroscience and the use of wearable technologies in consumer research. This analysis, which examines publication patterns, citation networks, and thematic evolution, reveals how discourse in the field has evolved and identifies key areas ripe for future research. By doing so, the analysis acts as an essential tool for outlining the field's progression, pinpointing literature gaps, and suggesting how incorporating the Technology Acceptance Model (TAM) into consumer neuroscience and wearable technology research can open new avenues for enhancing consumer well-being. In a recent conference paper, Alvino et al. (2023) attempted to apply TAM to understand how marketing professionals adopt consumer neuroscience tools. Building on their work, we suggest broadening the range of tools in consumer neuroscience to include devices that collect physiological data (Clithero et al., 2024), indicating the potential for technological advances from the biomedical sector to influence consumer behavior research, offering significant benefits to individual and societal well-being on a wider scale.

Unveiling the Dynamics of GPT Technology Adoption: Assessing Trust in Technology and Self-Efficacy's Influence on Consumer Behavior

FRANCESCA CELIO¹ FRANCESCO RICOTTA²

Abstract

This study explores the dynamics of user engagement with Chat GPT, an AI-powered chatbot, through the lens of trust, self-efficacy, knowledge, and technology acceptance. Utilizing a task-based experimental design, we examine how these dimensions influence technology adoption among two distinct user groups: "Current Users" and "New Users". Our research seeks to unravel the influence of these variables on individual behavior and the intricacies of decision-making in the realm of AI chatbot engagements, delivering comprehensive insights into the catalysts and impediments to adopting technology. The present research makes a valuable contribution to the wider thematic of consumer-technology relationship, emphasizing the need for enhancing digital literacy and trust to promote wider acceptance and satisfaction with emerging technologies both for current and new users.

Key words: Chat GPT; Knowledge; Self-Efficacy; Trust; Technology Adoption; Protocol Analysis

Framing of the research. *Understanding how consumers interact with technologies based on intelligent agents as well as artificial intelligence, has attracted a wide debate over different scholars (Mariani et al., 2022; Coombs, 2020, Puntoni et al., 2020). Several scholars have directed their research towards different variables, including knowledge, technology acceptance, self-efficacy, and trust. In this paper, the aim is to investigate these variables, the relationships between them, and the consequences they exert on consumer choice.*

Cegarra-Navarro et al. (2014) define knowledge as "the knowledge and ability to use specific technologies such as the Internet". Technological knowledge is not only about understanding emerging technologies, but also about the ability to use them. Furthermore, knowledge can contribute to improving user interaction, technology acceptance and facilitating personal decisions in multiple contexts (Kelly et al., 2023). Consequently, this study aims primarily to explore how pre-existing knowledge and experience play a role in creating a favorable environment for the acceptance of technology. Within a setting marked by significant technological progress and swift changes, users form new preferences through utilizing the comprehensive scope and detailed insights of accessible knowledge (D'Angelo and Valsesia, 2022).

According to Tuu et al. (2021) there is a positive association between technology experience and acceptance of mobile technology, as consumers with high technology experience often perceive the use of mobile devices as easier, more convenient and useful. Technological experience is seen as a combination of ease of use, access to knowledge, and flexibility in adapting to new situations.

Consumers with higher expertise associated with the applied technology are more likely to obtain more effective results, since their knowledge foundation is highly developed. "The facilitation of AI adoption is determined by a variety of factors, including users' knowledge, available resources, and the accessibility of guidance from marketers or peers (Mahardika et al., 2019). Berkowsky et al. (2017) point out that consumers with high knowledge are more inclined to demonstrate a positive attitude due to their familiarity and experience.

A high level of technology knowledge could increase users' confidence and their ability to effectively use the technology, thus promoting the overall improvement of personal ability.

Furthermore, Nyberg et al. (2022) suggest that knowledge positively correlates with self-efficacy, which in turn is a significant predictor of performance. They link scientific competence with self-efficacy, explaining that it encompasses two dimensions: knowledge of scientific content and the ability to reason scientifically. Their research highlights that positive self-efficacy is connected not only to academic achievements but also influences motivational processes, self-regulation strategies, self-perceptions, and interests, as evidenced by the works of Bandura & Schunk (1981), Klassen & Usher (2010), Pajares & Valiante (1997), and Schunk (1995). The authors showed how the investment in persistence and effort in completing challenging tasks is higher in individuals with a positive level of self-efficacy (Pajares, 1996). Based on Bandura's theory of social cognition (1977), self-efficacy is classified as a competence belief and is understood as the

¹ Sapienza University of Roma
e-mail: francesca.celio@uniroma1.it

² Sapienza University of Roma
e-mail: francesco.ricotta@uniroma1.it

belief in one's ability to cope with a future situation or task. The results show significant relationships between task-specific self-efficacy in scientific reasoning and performance in scientific reasoning, as well as between task-specific self-efficacy, scientific content knowledge and performance in scientific content knowledge.

Self-efficacy is characterized as the conviction in one's capability to accomplish a specific task under given circumstances, reflecting confidence in one's abilities rather than the actual possession of specific skills (Bandura, 1977). Within the framework of Self-efficacy Theory, such a construct is more precisely conceptualized as the confidence an individual has in their capacity to effectively influence their environment through the successful completion of tasks or resolution of problems. This concept plays a pivotal role in theories of motivation, impacting areas such as academic motivation and career decision-making

When people with high self-efficacy achieve a certain goal, there is a good chance that their next goal will be more challenging. And if a goal is not achieved, the way people react varies from person to person. Some respond with renewed commitment, others with despair and apathy. The results can be self-reinforcing. On the other hand, successfully achieving goals can increase self-efficacy and thus the future likelihood of success. Numerous investigations have empirically confirmed the impact of self-efficacy on technology adoption behaviour (Holden et al., 2011; Zhang et al., 2017; Ellen et al. 1991). Consumers with high self-efficacy show a stronger motivation to perform specific tasks than those with low self-efficacy, indicating a higher confidence in achieving positive outcomes (Noe and Wilk 1993; Tannenbaum et al. 1991). Consumers with an elevated degree of self-efficacy in technology demonstrate greater involvement in the use of technology-based services (Dabholkar and Bagozzi, 2002), accompanied by a more favourable attitude and a greater intention to use such services than those with a lower level of self-efficacy in technology. It clearly emerges that the consumer's level of self-efficacy may anticipate the adoption behaviour of new technologies by individuals.

In contrast, Roy et al. (2019) focus on users who do not have high knowledge. Their research suggests that consumers with low technology knowledge may show lower levels of self-efficacy and trust towards new technologies, which may lead to lower technology acceptance. Their lack of familiarity and experience with technology may lead to uncertainties and doubts about their ability to use new technologies effectively, their trustworthiness and the usefulness of the technology. In essence, consumers who are less familiar with the technology used tend to have less confidence and feel less secure in its use, which may make them less likely to accept it.

It follows that unfamiliarity directly influences the practice and perception of new technologies, which suggests that greater familiarity with the technology might encourage more deliberate practice (Colvin, 2010).

According to the author, in fact, years of deliberate practice can even change an individual's body and mind. Several studies show that by continuously repeating the right exercises and putting them into practice, an average professional can transform into an exceptional performer (Bandura, 1977; Colvin, 2010 ; Kodden, 2014).

Analyses show that experience with technology, autonomous learning and socio-economic background are determinants of variations in ICT self-efficacy. These findings suggest that ICT self-efficacy is closely related to computer literacy, even when controlling for other baseline characteristics and contextual variables.

These results suggest a very clear distinction between computers self-efficacy and computer competence, showing that an individual's comfort level with computer use may not match her/his capabilities to properly handle the computer. In other words, a person might feel confident in using digital technologies without necessarily having a thorough knowledge of them.

In addition, research emphasize how ICT competence substantially anticipates ICT self-efficacy. Extended engagement with technology gradually enhances understanding and skills, leading to more effective use of Information and Communication Technology (ICT) across various contexts. Bandura (1977) further notes that an individual's perceived or potential capability to adeptly handle a product is mirrored in their evaluative and behavioral responses towards the product.

Therefore, self-efficacy is believed to play a significant role in shaping the development of beliefs and behaviors related to intentions to use technology, while also having an indirect impact on the perceptions of its ease of use and its perceived value. Self-efficacy is pivotal for an exhaustive comprehension of how individuals perceive and adopt new technologies. Individuals with higher levels of self-efficacy are more likely to view new digital technologies as user-friendly and beneficial, which diminishes their resistance to change and enhances their readiness to embrace these innovations. Notably, consumers who are more receptive to AI technologies exhibit a more pronounced positive influence on their level of self-efficacy compared to those who are less receptive (van Esch et al., 2021). This indicates that self-efficacy not only directly influences individuals' attitudes and behaviors towards technology but also does so indirectly. By nurturing confidence in one's capabilities, the encouragement of adopting and utilizing new technologies can be significantly enhanced. People's confidence in their ability to use technology (self-efficacy) and their perception of how easy it is to use (ease of use) affect their decision to adopt new technologies.

However, self-efficacy is not the sole factor that matters: Trust also plays a significant role. According to Tams et al. (2017), trust can decrease feelings of emotional arousal and anxiety, increasing self-efficacy (Kelly and Noonan, 2008). Trust helps reduce negative emotions and promotes self-efficacy (Bandura, 1977; Marakas et al., 1998). Self-efficacy in using technology can have different impacts on how well technology is used after its adoption. Self-confidence affects how technology is used after adoption, leading to better job performance and successful management of strategic changes

In their study, Zheng Yan et al. (2014) describe trust as a complex concept involving security, belief and expectations about reliability, integrity, protection, capability, and other characteristics of an organization.

With his contribution, Areej AlHogail (2018) points out that trust can be perceived as a significant factor that influences the behavioral intention to use an IoT technology and has a strong effect compared to other concerns such as privacy. Falcone and Sapienza (2018) indicated several reasons why users may not grant high levels of trust, as they may fear that a task will not be completed as expected or at all, or even that harm will be caused. Consumer acceptance of new technologies relies heavily on building their trust: lower levels of trust in the proposed technology can hinder its adoption.

This research aims to provide a novel perspective on the relationship between consumers and their attitudes towards technology, specifically focusing on three variables: trust, self-efficacy and technology adoption.

Purpose of the paper. The use of advanced technologies, specifically Chat GPT, can influence consumers' behaviors. Building on existing knowledge, three critical factors influence the attitude toward the use of Chat GPT: trust in technology, perceived usefulness, and self-efficacy. Given that GPT technology is a relatively new category for consumers and has not yet been thoroughly explored, our research aims to delve into how users' prior knowledge impacts their perceptions, evaluations, and decision-making processes when using Chat GPT. This paper aims at exploring the key variables of technology acceptance, self-efficacy and trust, and how those are framed depending on the level of users' pre-existing knowledge.

Methodology. This study adopts an exploratory approach aimed at understanding the interaction processes between individuals and a complex technology like AI. In particular, the goal is to understand the mental processes that drive the use of AI and then to explore its antecedents. Consistent with the theoretical assumptions cited, we believe that the research can be useful in characterizing the subjective drivers that fuel the antecedent of AI adoption: self-efficacy and trust. To better address this task, we run four personal in depth interviews based on protocol analysis technique.

This approach allows users to verbalize their thoughts – the think aloud method - while completing a specific task. By doing so, we aim at gaining insights into the cognitive processes that shape users' interactions with Chat GPT. Protocol analysis is a well-established technique in cognitive psychology, with researchers like Newell and Simon (1972) and Ericsson and Simon (1980, 1993) emphasizing its value for investigating cognition from an information-processing perspective (Smagorinsky, 1998).

The interviews took place in October 2023. The study involved four participants, split into two groups based on their familiarity with ChatGPT. Group 1 comprised users knowledgeable about ChatGPT's capabilities and applications, while Group 2 consisted of users with no prior experience and knowledge on the AI chatbot. This distinction allowed us to examine variations in their approaches, experiences, and perceptions between novices and expert users.

We formulated the questions using wording that refrained from expressing either agreement or disagreement with their responses, ensuring no pauses occurred between questions. To adhere to the protocol analysis meticulously, we established a set of procedures both prior to and during the interviews. Before initiating each protocol, we assigned a unique code to each interviewee and prepared a protocol sheet detailing the interview date, along with the start and end times of each session. The interviews averaged 14 minutes in duration, with the longest extending up to 18,19 minutes and the shortest lasting 11,33 minutes.

Participants engaged in a task where they utilized the AI assistant Chat GPT to plan a trip. Throughout the process, they shared their thoughts, choices, questions, and approaches in real-time.

The study has been divided in four steps as follow:

- (a) **Preparation and Orientation:** All participants learnt about the study's goals and how Chat GPT works. They received specific instructions on the task they would perform (Figure 1). They had a reference table with tasks and subtasks to follow, in order to plan a trip.

Figure 1. Reference table with tasks and subtasks

Generic Task	
1.	Choose a destination to visit
Specific Tasks	
2.	General information on required visas and mandatory/recommended vaccinations
3.	Identify the best time of year to go visit
4.	Choose the area(s) to stay in
5.	Find restaurants serving local cuisine
6.	Identify the main places of interest
7.	Check the weather to decide what clothes to bring
8.	Choose any additional activities to do

Source: Our elaboration

- (b) **Interaction Sessions:** Each participant had a one-on-one conversation, without any distractions, with Chat GPT while planning a trip. During these sessions, participants shared their thoughts as part of a "think aloud" process.

- (c) *Data Collection: The interactions were recorded and analyzed later. Participants' verbalizations were transcribed and categorized in two types of events - actions and objectives - based on predetermined variables, including trust, self-efficacy, and technology acceptance.*
- (d) *Follow-up interviews: After the sessions concluded, users participated in a debriefing interview. This interview aimed to gather their insights on the overall experience, their satisfaction and their perspectives on the variables investigated in the study, to have a more profound comprehension on how familiarity with new technology affects the users' experience.*

Results. *In the results section of this study, the interactions of four subjects with Chat GPT 3.5 for the purpose of plan a trip are analyzed, using the protocol analysis method. Participants fell into one of two groups based on their familiarity with the chatbot: "Current Users" who were very familiar with Chat GPT and "New Users" who had little to no prior knowledge. The study aims to understand how factors like trust, self-efficacy, and technological adaptation influence the user experience, and how these factors change based on the users' pre-existing knowledge of the technology.*

I. Trust

The level of trust towards Chat GPT significantly diverges between the two groups. "Current Users" exhibit trust that has matured through repeated use of the platform, translating into specific expectations regarding the system's functionalities and limitations that the chatbot has to offer, such as the inability to display maps or to have direct links with other websites for obtaining an accurate price estimate. The interviewee No. 2 shows a form of surprise upon seeing the proposed results. However, he/she retains unaltered trust in the tool and asks for the information to be specified in a more specific field: "So I hadn't chosen whether I wanted to go to the Mediterranean or the Atlantic, and I'm more interested in Costa del Sol. So, I will ask for more information, and I will say that I am interested in Costa del Sol".

This category highlights a greater critical awareness towards the responses received and, when expectations are not met, negative feelings towards the chatbot are generated (e.g., "Ah... It does not show this information, I need to look it up by myself"; " However, he can't give me the answer").

Conversely, "New Users" rapidly develop trust based on the accuracy and relevance of the information received, despite a previous lack of familiarity with the interface. Their positive experience, culminating in informative satisfaction, underscores the efficacy of Chat GPT in meeting informational needs, even without prior interactions with the AI powered chatbot (e.g., "It is explaining strategies to get cheaper flights, also clearing the research history is useful. Great, I will do this"; "It is suggesting me many alternatives"; "I am very satisfied, it gives very detailed information and even more choices. I give it positive feedback, I like it.").

II. Self-Efficacy

The self-efficacy demonstrated by subjects reflects differences in the approach to using Chat GPT. "Current Users" exhibit high self-efficacy levels, navigating the interface easily and with confidence and conducting detailed searches relevant to their objectives, resulting in longer interaction times. This behavior indicates a greater propensity to deeply explore the platform's informational capabilities and all the functions that it has to offer. During the hotel search phase, respondent No. 2 asked about the best areas for accommodation and accepted one of the options suggested by the chatbot, without questioning the reliability of the information provided. At that moment, they were pleasantly surprised ("Ah, it even directs me to hotel booking sites") by the ability to seamlessly continue their search on hotel booking websites recommended by Chat GPT, finding it beneficial to proceed directly from there without the need to open a new search tab. On the other hand, "New Users" display an increase in self-efficacy levels throughout the experiment. The ease of use and intuitiveness of the interface facilitate quick adaptation, enabling individuals without prior experience to feel capable of efficiently using the technology. Initially, despite a brief initial explanation of Chat GPT's functionality, the non users struggled to understand how the chat bot worked. The users struggling with understanding which type of tasks Chat GPT could do, initially asked more general questions before becoming more familiar with the chatbot's functionality. Subsequently, as the depth of the responses was better understood, more complex queries were developed, which at some point would allow the users to bypass some steps in the research by having two or more questions in one single query. There is observable evidence of increasing efficacy with which inquiries are posed to Chat GPT. The initial questions tend to be generic, such as "I would like to visit Paris, when is the weather good?" However, subsequent queries, following a period of acclimatization to the chatbot and a realization of its capabilities, become more specific and pragmatic: "How and where can I purchase tickets at a reasonable/discounted price?" Consequently, new users have achieved an increasingly higher level of self-efficacy, attributable to a growing awareness of the applications and potentiality of Chat GPT.

III. Technology Adoption

The propensity to adopt Chat GPT as a support tool in organizing trips is influenced by a combination the variables of trust and self-efficacy. "Current Users" approach the platform with a critical but informed attitude, demanding advanced functionalities and carefully evaluating the accuracy of the information provided, sometimes comparing it with information previously obtained from other channels ("as a starting point is very valid, but I still want to verify this information or look for more, to make sure I haven't missed anything" – Interviewee No. 1). This group represents a case of mature technological adoption, where prior experience shapes expectations and interaction with the chatbot.

Conversely, "New Users" demonstrate openness to adopting Chat GPT, motivated by the immediate informational efficacy experienced and the surprise generated by the speed and ease of use. Respondent number 2 experienced a moment of surprise when seeking advice regarding the local culinary specialties, due to the fact that he/she had never tried such dishes and consequently lacked any expectations: "ok, obviously I do not know any of these dishes, but they are described in a clear way, so I am able to imagine them in my head. My interest is piqued by the Pad Thai, because i really like

noodles, and I would not have understood that they were similar if I did not read the description." In this instance, Chat GPT offered a concise yet accurate explanation, facilitating the user's formation of expectations concerning the food and providing an answer to a question pertaining to an as-yet unarticulated need regarding the specific ingredients and appearance of the dish. This initially positive experience suggests a higher probability of integrating Chat GPT and similar technologies into future activities, denoting an initial phase of technological adoption driven primarily by perceived usability and a positive user experience.

Research limitations. Despite its insightful contributions, several limitations should be acknowledged due to its current development stage.

First, the limited sample size and specificity may restrict the generalizability of the findings. More diversified or larger samples might be useful to enhance the representative power.

Secondly, the methodology developed around protocol analysis gives good in-depth qualitative insights but lacks the wider landscape that results from quantitative means could bring for statistical generalization. We are actively working on the further development of this analysis and on the design of a quantitative analysis model.

Furthermore, focusing such research only on ChatGPT would limit the generalizability of its relevance for other new technologies. Broadening the research to other technologies could enrich the results of the study.

In that way, while the present study offers salient first insights into how users interact with AI chatbots, duly considered limitations will balance the findings and guide future research directions that may be attempted to be advanced within this rapidly evolving domain of consumer-technology relationships.

Managerial implications. The findings of this study highlight that trust, self-efficacy, and technological adoption are key factors in users' interactions with Chat GPT. Understanding these variables provides crucial insights for the development of strategies aimed at improving user engagement and refining technological platforms according to users' needs and expectations.

This aligns with the notion that trust in technology not only reduces hesitancy but also fosters a sense of security and reliability among users (Tams et al., 2017; Areej AlHogail, 2018).

Moreover, the role of prior knowledge and experience in shaping user interaction with Chat GPT cannot be overstated. Our findings indicate that technology-educated users have a nuanced understanding and a critical approach towards adopting and using Chat GPT, highlighting the importance of technological knowledge in navigating the complexities of modern digital tools. The study also sheds light on the initial barriers faced by users with limited technological and functional knowledge of Chat GPT. The progression from a state of uncertainty to one of confidence and trust in Chat GPT's capabilities illustrates how important intuitive design and user experience are in mitigating these barriers, affirming the usefulness of ease of use and perceived utility in the adoption process. Recognizing the diversity in users' technological background and leveraging this variability can lead to more personalized and efficient user interactions. Advanced users could be offered more complex functionalities, while newcomers might benefit from a more guided experience.

Originality of the paper. This research contributes to the ever-present discourse on consumer-technology interaction by highlighting the interrelated roles of knowledge, self-efficacy, trust, and technology acceptance. Our work integrates these factors within the framework of AI chatbot interaction, offering a comprehensive understanding of how they collectively influence technology adoption and user satisfaction.

This integrated approach not only advances our theoretical knowledge of consumer-technology relations but also provides practical insights for enhancing user interaction with emerging technologies. Furthermore, by differentiating between "Current Users" and "New Users," this study offers nuanced perspectives on the adoption and utilization of Chat GPT, highlighting the importance of user-centric strategies in technological design and implementation.

Investigating Perceptions of Brand Personality and Consumer Reactions in the Automotive Industry by ChatGPT

ALESSANDRO SIGNORINI¹ ALESSANDRO FERI² ANGELO BACCELLONI³ ELISA PUVIA⁴

Abstract

This research explores brand personality perceptions in relationship with the generative AI platform ChatGPT. The initial phase of the research is to confirm whether ChatGPT manifests distinct brand perceptions and to comprehend how the brand perceptions are shaped. Once ChatGPT is shown to form brand perceptions, these perceptions are presented to consumers in the form of brand statements. The second phase of the research is to analyze the effects on consumers when informed that these statements are generated by ChatGPT compared to traditional search engines. This research is developed within the context of the automotive industry, with a specific focus on fourteen automotive brands listed in Interbrand's 100 Best Global Brands of 2022. Brand perceptions generated by ChatGPT are investigated employing a semi-structured approach, where direct queries are posed to ChatGPT to gain insights into its processing of brand perceptions. To analyze and evaluate ChatGPT responses, Aaker's (1997) well-established framework of brand personality, encompassing five dimensions, is applied. The effects on consumers are examined using an experimental design with participants divided into two groups. Both groups are presented with identical brand statements from three automotive brands. The only difference is that participants will be told that the statements are derived from ChatGPT or a traditional search engine. The study will conclude with in-depth interviews to the participants. The study's significance lies in understanding how ChatGPT interprets and presents brand perceptions, considering the potential influence this AI platform may have on shaping consumer attitudes, particularly while it evolves into a search engine. As consumers increasingly rely on ChatGPT for product evaluations and post-purchase interactions with brands, the platform offers valuable insights into brand personality when prompted, facilitating the rating of different brand personality dimensions.

Key words: Artificial Intelligence 1, ChatGPT 2, Brand Personality 3, Brand Comparison 4, Automotive Industry 5.

Framing of the research. ChatGPT is an Artificial Intelligence (AI) platform developed by OpenAI and introduced to the public in November 2022 (Pavlik, 2023). ChatGPT has attracted significant attention due to its utilization of natural language processing and machine learning techniques to enable interactive conversational capabilities (King, 2023). In academic literature, ChatGPT has been defined as “a large language model developed by OpenAI that uses deep learning techniques to generate human-like responses to text-based prompts. It is trained on a large corpus of text data using unsupervised learning techniques to learn the statistical patterns and regularities of human language and use that knowledge to generate coherent and contextually appropriate responses” (Paul et al., 2023: 1213). Through the analysis of available information and the utilization of learning mechanisms, ChatGPT generates text-based responses to user inquiries. Its rapid adoption has been remarkable, with over one million users registering on the platform within five days of its launch, surpassing the growth rates of successful platforms like Instagram, Facebook, and TikTok (Bailey, 2023).

The advent of ChatGPT has had a profound impact on the financial landscape, particularly in the domain of artificial intelligence investments. Shares associated with AI ventures experienced a substantial surge in value, driven by ChatGPT's demonstrable potential in language processing applications (Hajric and Shen, 2023). Well-known economists have even posited that ChatGPT may be the most disruptive technology of the decade, similar to a “calculator in writing” in the words of Brynjolfsson (Aldrick, 2023). While acknowledging certain characteristics of a transient investing fad in ChatGPT, Morgan Stanley recognizes that technology holds the potential to revolutionize text-writing and information-gathering (Ponciano, 2023).

In the domain of information retrieval, ChatGPT is widely regarded as more advanced than Google search engine (Paul et al., 2023). While Google inundates consumers with extensive information that requires manual filtering, ChatGPT stands out by generating tailored and coherent responses that align with users' queries. As ChatGPT

continuously self-improves and integrates real-time data, there exists a tangible possibility that it could eventually surpass Google in terms of information retrieval (Paul et al., 2023). As ChatGPT progresses towards its integration into a search engine, research suggests that consumers will increasingly rely on this platform during their decision-making process and include it in their consumer journey (Dwivedi et al., 2023). Unlike other search engines, ChatGPT can answer customer inquiries directly rather than providing a list of results. It may therefore offer a unique opportunity for marketers to influence consumers at various stages of their purchasing experience. Notably, information search is crucial in the consumer decision-making process as consumers try to decrease the perceived risk associated with a purchase by gathering brand-related information from online and offline sources (Basso et al., 2019; Hansen, 2005; Puccinelli et al., 2009). As ChatGPT can be used as a research-gathering tool, marketers can incorporate the AI interface into relevant touchpoints to enhance AI-based customer conversations and influence customers' decisions with highly relevant content. Dwivedi et al. (2023) highlight numerous potential applications of ChatGPT in marketing, including the development of targeted marketing campaigns, the optimization of content marketing and chatbot-based customer service, the enrichment of the customer experience, keyword generation and recommendations, the conduct of marketing research, and brand comparison analyses (Dwivedi et al., 2023).

The potential of ChatGPT appears promising in the marketing field, although marketers face specific challenges. While ChatGPT offers a valuable tool for content curation, similar to Google's functionality, its use of robust database models and AI-driven learning algorithms suggests that traditional approaches, such as keyword-based content or search engine marketing, may not deliver the desired results within the ChatGPT structure. Consequently, successful marketing strategies necessitate a well-defined collaboration between marketers and OpenAI to effectively navigate the complexities of advanced AI algorithms (Dwivedi et al., 2023). Managing the alignment, or potential misalignment, between the intended and perceived brand personality becomes crucial for marketers, as any discrepancies can impact consumer perceptions and potentially originate reputational harm. According to Paul et al. (2023), ChatGPT can offer several advantages for consumers. Primarily, it can elevate consumer engagement by providing an interactive experience that surpasses traditional communication methods. Additionally, it can enhance customer service by delivering prompt responses and efficient issue resolution. Furthermore, ChatGPT can facilitate shopping personalization by generating tailored recommendations, marketing messages, and shopping tips based on consumer behavior and preferences (Konya-Baumbach et al., 2023). The platform can also foster social interaction and communication practices. (Haluzá and Jungwirth, 2023). In conclusion, ChatGPT can improve marketing campaigns by generating compelling messages that deeply resonate with consumers, leading to heightened engagement and conversion rates. ChatGPT, despite its numerous benefits for consumers, also shows several potential drawbacks that demand careful examination (Paul et al., 2023). Bias poses pressing concern since ChatGPT can reinforce biases inherent in its training data, resulting in unfair outcomes and cases of discrimination (Aker et al., 2021; Ray, 2023). Furthermore, the generation of misinformation by ChatGPT raises issues of trustworthiness, especially in contexts where accuracy and truthfulness are essential, such as in marketing claims and product information (Floridi, 2019). The model's limited contextual understanding may produce nonsensical or inappropriate responses, with potential risks for brand reputation. Addressing privacy issues is important given the collection and storage of consumer data, which necessitates robust data protection measures. Ethical considerations encompass the accountability of AI platforms, the presence of biases in internet-based data, and potential impacts on users' moral judgments (Bredibach and Maglio, 2020). Lastly, ChatGPT's capabilities can be exploited for malicious purposes, such as generating phishing emails or deceptive content, highlighting the importance of responsible and ethical usage.

Purpose of the paper. Given the potential utility for both academic and non-academic pursuits, ChatGPT has become a "cultural phenomenon" (Thorp, 2023, p. 313). By utilizing ChatGPT's capabilities, this research seeks to offer valuable insights and implications for businesses to better understand and manage their brand personality perceptions, thus enhancing their brand strategies in the digital age. Adopting an original perspective, the aim of this study is to investigate whether ChatGPT exhibits human-like attitudes, namely brand-specific perceptions, and, if so, to explore the underlying mechanisms through which these perceptions are processed by consumers. By investigating the interplay between ChatGPT and brand perception, this research contributes to the growing literature on the impact of AI platforms on consumer behavior and related brand management practices (Dwivedi et al., 2023; Gursøy et al., 2023; Konya-Baumbach et al., 2023; Mich and Garigliano, 2023; Paul et al., 2023).

The present paper aims to fill a significant research gap by examining the impact of the AI platform ChatGPT on branding strategies, an area that has been largely overlooked in both academic and non-academic literature. To the best of our knowledge, no previous studies have examined whether ChatGPT possesses distinct and independent perceptions of established brands, along with the mechanisms it uses to process these perceptions. As emphasized by Paul et al. (2023: 1219), "researchers could examine the extent to which ChatGPT-generated responses influence consumer behaviour, such as purchase decisions, product evaluations or brand perceptions". Similarly, Dwivedi et al. (2023: 16) state that "studies should explore how generative AI technologies can benefit marketing in customer services, customer engagement and experience, content curation and development, marketing research, lead generation, commerce, and promotional activities". By delving into the process of brand perception by ChatGPT, this study takes a first crucial step toward understanding how the platform demonstrates human-like attitudes, specifically focusing on brand-specific perceptions of brand personality.

In line with the study's objective, we examine the potential for ChatGPT to act as a medium for brand values, embodying the characteristics that define automotive brands and thus shaping the way consumers may relate to them (Manis and Madhavaram, 2023). Through this lens, the research not only contributes to theoretical advancements by

highlighting the intersections of AI and brand personality but also offers actionable insights for marketers aiming to integrate AI into their strategic toolkit (Chintalapati and Pandey, 2022). To examine the potential brand perceptions of ChatGPT, the well-established framework of brand personality dimensions proposed by Aaker (1997) is adopted. Brand personality is defined as “the set of human characteristics associated with a brand” (Aaker, 1997: 347). This framework allows the identification of distinct typologies of brand personalities and assigns a quantifiable scale to each dimension, enabling a comprehensive understanding of brand perception. By incorporating a scaling system, the framework provides a structured method for theoretical generalization regarding the symbolic utilization of brands (Aaker, 1997; Freling et al., 2011; George and Anandkumar, 2018; Radler, 2018; Saeed et al., 2022). Moreover, the framework and its associated scales can be readily extended to various product categories, ensuring its versatility and applicability.

Aaker's framework comprises five dimensions that exhibit high representativeness, reliability, and variance in the evaluation of brand personality: sincerity, excitement, competence, sophistication, and ruggedness. The dimension of sincerity reflects attributes such as honest, down-to-earth, and wholesome, which are essential for establishing a positive brand image. Excitement emphasizes characteristics such as daring, spirited, and imaginative, which contribute to a brand's capacity to evoke enthusiasm and engagement among consumers. Competence pertains to qualities associated with reliability, intelligence, and success, signaling a brand's capability to deliver superior performance and meet customer expectations. Sophistication embodies traits of elegance, upper class, and charm, conveying brand's aspirational and premium qualities. In conclusion, ruggedness represents attributes of toughness, durability, and resilience, which portray a brand as robust and suitable for challenging environments (Aaker, 1997).

By employing Aaker's (1997) framework, ChatGPT's perception of brand personality can be comprehensively explored in the automotive industry. This framework facilitates an analysis of the extent to which ChatGPT aligns with or deviates from the identified dimensions and their associated scales, thus providing valuable insights into the brand perceptions that may emerge. Moreover, through an examination of the alignment between the framework's dimensions and human personality dimensions, as identified by Briggs (1992), this research aims to gain a profound understanding of how ChatGPT's brand personality can embody and align with specific brand attributes. Three brand personality dimensions align with three dimensions of the “Big Five” human personality traits proposed by Briggs (1992). Agreeableness and sincerity both reflect warmth and acceptance, while extroversion and excitement indicate sociability, energy, and activity. Conscientiousness and competence embody responsibility, dependability, and security. Conversely, the dimensions of sophistication and ruggedness deviate from any of the “Big Five” traits identified by Briggs (1992). This pattern suggests that brand personality dimensions may operate differently or influence consumer preference for distinct reasons. Notably, dimensions like sincerity, excitement, and competence tap into innate aspects of human personality, while sophistication and ruggedness align with traits that individuals aspire to but may not necessarily possess. These insights stress the complexity of brand personality and indicate that different dimensions may play diverse roles in shaping consumer perception and preference. In recent years, scholars in the domain of social psychology have extensively examined how people form impressions about brands. Kervyn et al. (2012) posited that consumers establish relationships with brands similarly to those with individuals. In their theorization, they adapted the Stereotype Content Model (SCM) (Fiske et al., 2002), which is one of the most influential theoretical frameworks in the field of social cognition. According to the model, individuals perceive social groups by focusing on two fundamental dimensions: warmth and competence. Individuals rapidly assess warmth, which refers to the perceived intentions of others, and competence, which pertains to the ability of others to carry out those intentions. Warmth includes traits such as helpfulness, sincerity, friendliness, and trustworthiness, while competence encompasses efficiency, intelligence, conscientiousness, and skill. Kervyn et al. (2012) proposed that the model governing social perception can be adapted and extended to brand perception. Therefore, they developed the Brands as Intentional Agents Framework (BIAF) by modifying the Stereotype Content Model to suit the brand perception context.

Aaker's scale shows similarities with the Stereotype Content Model, particularly in the alignment of the competence factor with competence dimensions and the sincerity factor with the warmth dimension. The ruggedness factor combines low warmth and high competence, a combination that has been associated with stereotypical masculinity (Eagly and Steffen, 1984). The BIAF suggests that brands vary in their perceived intentions and ability to fulfill those intentions. Existing evidence suggests that personality scales akin to Aaker's are well-suited for detailed descriptions of individual brands with a focus on their attributes. Conversely, social perception models, such as the BIAF, offer researchers the possibility of assessing the perception of multiple social objects, facilitating a comprehensive comparative analysis of these objects within a broader landscape. By employing Aaker's (1997) framework, ChatGPT's perception of brand personality can be comprehensively explored in the automotive industry. This framework facilitates an analysis of the extent to which ChatGPT aligns with or deviates from the identified dimensions and their associated scales, thus providing valuable insights into the brand perceptions that may emerge. To achieve this, the methodology incorporates various techniques to uncover the brand personality attributes and explore their implications for effective brand strategies in the digital age.

Methodology. The present study has two separate research objectives. The first objective is to evaluate ChatGPT's perceptions of brand personalities in one specific industry. In detail, it is evaluated if ChatGPT holds well-defined brand perceptions within the automotive industry and how the brand perceptions are formed. Having demonstrated that ChatGPT exhibits brand perceptions, the second objective of the research is to test the perceptions on consumers in

comparison with traditional search engines, in this case, Google search engine. At the current stage of the research, the first part of the research has been completed, while the second part is yet to be conducted.

The selection of the automotive industry is mainly driven by the significant academic interest in branding within this industry. Relevant studies have explored different aspects of branding in the automotive field, for example, research explored brand antecedents in the search for uniqueness (Nikhashemi and Delgado-Ballester, 2022), value and pricing in the consumer brand relationship (Hamzah and Pontes, 2022), brand personality in emerging markets (Ha and Janda, 2014), and the impact of brand reputation and brand personality congruence on brand loyalty (Kuenzel and Halliday, 2010). In addition, the automotive industry invests significant financial resources in brand strategies (Reportlinker, 2022) that are essential to gain a competitive edge in a global oligopolistic market (Carr, 2022). Consumer choice in the automotive industry is also complex and time-consuming because of the high value of the transaction compared to the average annual budget (Heath and Soll, 1996) and the association with high social status (Hannan, 2015). Consumers engage in relevant and complex searches for information when choosing a car and tend to rely upon search engines (Yoo, 2014), and, in the future, may rely on AI-generative search engines, such as ChatGPT.

Specific brands in the automotive industry were selected according to their inclusion in the 100 Best Global Brands 2022 proposed by Interbrand (2022). Interbrand employs a method that evaluates financial performance, brand influence, and consumer loyalty to discern and rank the 100 most valuable brands worldwide (Interbrand, 2023). The list of brands is chosen because it encompasses both luxury and budget brands, as well as brands from a variety of geographic locations offering a comprehensive and diversified representation. A purposive sampling technique was employed to select the sample from the Interbrand list. This sampling approach was regarded as most suitable for the research topic, as it focuses on brand personality impressions in the automobile sector. Fourteen brands from the car industry were extracted from the list. Through purposeful sampling, automobile brands with a high brand presence in the global market were included in this study. The sample size follows the principle of data saturation, "saturation will occur when few or new data are being generated" (Murray, 2010: 16). The sample size was expanded until data saturation was reached (fourteen car brands), ensuring that no new data were being generated (Fusch and Ness, 2015; Langley, 2004; Trotter, 2012).

The research aims to address the following research questions:

RQ1. How does ChatGPT perceive brand personality in the automotive industry?

RQ2. How does ChatGPT categorize existing automotive brands according to Aaker's (1997) framework?

RQ3. How does ChatGPT rate existing automotive brands according to Aaker's (1997) framework?

RQ4: Do consumers perceive brand statements differently when they originate from ChatGPT compared to traditional search engines in the context of automotive brands?

RQ5: How do consumers' perceptions of automotive brands differ when they are exposed to brand statements generated by ChatGPT compared to those from traditional search engines?

The first objective of the research, namely, assessing ChatGPT perceptions of brand personalities in the automotive industry, with the associated three research questions RQ1, RQ2, and RQ3, was achieved through a qualitative method. Indeed, this research employed a semi-structured interview approach, engaging in direct textual inquiries to understand ChatGPT's perceptions of brand personality in the automotive industry. The interviews were conducted remotely on the chatbot platform with all responses carefully recorded and analyzed. The adoption of semi-structured interviews allows for a comprehensive understanding of ChatGPT's perceptions, while also offering adaptability and flexibility during the inquiry process (Kallio et al., 2016). To develop the interview questions, a thematic analysis of the existing literature on brand personality was performed (Thomas and Harden, 2008). The interviews were organized into three parts, each aligned with one of the research questions. The first part sought to grasp ChatGPT's perceptions of brand personality in the automotive industry. The second part focused on how ChatGPT categorizes existing automotive brands according to Aaker's (1997) framework. Lastly, the third part aimed to comprehend how ChatGPT rates existing automotive brands as outlined in the framework.

Thematic analysis, a qualitative research approach facilitating pattern and theme identification within datasets, was employed to extract themes relevant to RQ1 and RQ2 from the collected data. Braun and Clarke's (2006) six-step method of thematic analysis guided this process, involving familiarizing oneself with the data, creating initial codes, identifying themes, evaluating themes, defining and labeling themes, and preparing a report. Thematic analysis is widely recognized in qualitative research (Braun and Clarke, 2006; Levac et al., 2010; Malterud et al., 2016). To address RQ3, ChatGPT was asked to score the brand personalities of the selected brands on a numeric scale for each dimension, following Aaker's (1997) framework. Subsequently, the scores assigned by ChatGPT for each dimension were collated and examined using descriptive statistics to generate a comprehensive data summary.

The second objective of the research, that is, testing the perceptions on consumers in comparison with traditional search engines, with the associated two research questions RQ4 and RQ5, was achieved through a quantitative method. Indeed, consumers will be tested in an experimental design setting. A convenience sample of 90 participants will be selected from students at undergraduate and graduate levels. Undergraduate students primarily be from Business, International Business, and Marketing Majors, while the graduate students will come from MBA and Masters in various business disciplines. Participants will be randomly assigned to two groups. Three separate car brands will be selected, one representing luxurious sporty positioning, one premium positioning, and one reliable and affordable positioning. Three diverse brand positioning are chosen to mitigate potential biases that specific typologies of brands may generate in the consumer's mind (Ariel et al., 2022). For example, consumers can perceive that luxurious brands should employ different brand touchpoints compared to affordable ones. Both groups will be presented to a series of brand statements

from these brands, but the first group will be informed that the brand statements originate from ChatGPT, while the second group will be told that the statements are from Google search engine. After one month, the groups will be reversed, the brand statements will be changed, with the first group now informed that the brand statements come from Google search and the second group from ChatGPT. The statements are changed to prevent confounding effects due to familiarity with the previous exposure (Ariel et al., 2002). After the experiment, participants will undergo in-depth interviews to explore and examine meaningful emerging themes (Denzin & Lincoln, 2005; Iphofen & Tolich, 2018; Toomer et al., 1993; Tracy, 2010).

Results. This section provides a summary of the research findings from the initial phase, while awaiting the results of the second phase.

The first phase of the research revealed valuable insights into how ChatGPT perceives and categorizes automotive brands, shedding light on its evaluation of brand personalities for the selected brands. Additionally, descriptive statistics were employed to analyze ChatGPT's ratings for each dimension within Aaker's framework, providing a comprehensive data summary. The findings contribute to the understanding of brand perception and AI-generated insights in the automotive industry, presenting relevant implications for brand strategies in this competitive market landscape.

Figure 1: ChatGPT's Scoring of Automotive Brands Based on Aaker's Dimensions

Figure 1 presents a comprehensive summary of the brand personality scores assigned by ChatGPT to fourteen automotive brands, utilizing Aaker's (1997) framework. The results of this study demonstrate clear distinctions among brands according to their distinct degrees of premium positioning and prestige. Luxurious and stylish brands (e.g., Mercedes, BMW, Porsche, Ferrari) are clearly distinguished from the reliable and affordable ones (e.g., Toyota, Honda, Nissan, Ford, Hyundai). Mercedes, BMW, and Audi are designated as exclusive and with sophisticated personality, which confirms the perception that these brands provide superior value propositions. These brands are awarded to this group based on their design and enduring commitment to technology. Yet, Mercedes stands alone in being luxurious, while BMW and Audi uphold a premium perception, but their defining feature revolves around high performance. In a separate premium positioning, Tesla and Land Rover are deemed as exclusive because of entirely different attributes, Tesla prioritizes innovation and environmental sustainability, while Land Rover emphasizes a longstanding tradition of premium SUVs tailored for rugged and adventurous terrains. Iconic sports cars such as Ferrari and Porsche constitute a distinct category as they are linked to a distinct level of social status, with Ferrari being the only brand connected with prestige. Despite Ferrari's notable involvement in Formula 1 and other racing categories, it is not tied to racing heritage, as is in the case of Porsche.

The remaining brands are categorized by ChatGPT as reliable and practical, displaying different levels of brand value attributes. Toyota is the only brand that embodies quality in its branding, similar to more prestigious brands, while Nissan distinguishes itself with stylish design. However, innovation is observed across several car brands despite diverse initiatives in new engine technologies. As an illustration, Toyota has been a pioneer in full hybrid engine technology with its Toyota Prius model. Currently, most Toyota cars feature advanced full hybrid engines, and the brand is making significant strides in hydrogen engine technology. In addition, Nissan introduced its Leaf model early on as a full-electric

product. Nevertheless, Nissan and Toyota are grouped with Ford, which has lagged behind in adopting new engines for its car models. While numerous car brands provide a variety of price ranges for their models, excluding premium brands, only Hyundai, Kia, and Ford are generally perceived as affordable. The term affordability likely refers to value-for-money models, where vehicles come equipped with numerous accessories and additional services and are offered at low or medium prices. Despite providing detailed personality traits for various car brands, ChatGPT showed a notable gap as it did not highlight the primary market segments of these brands. The platform acknowledged that certain brands, such as Ford, were tailored for "everyday use," but it did not focus on the distinct market niches or segments that each brand primarily targets. All the brands classified as reliable, practical, and innovative had no reference to their specific market segments, such as families, commuters, or professionals, for whom these brands design their vehicles. The primary consumers were not explicitly addressed by ChatGPT. This exclusion raises a critical aspect of brand positioning and marketing strategy.

Research limitations. Our study presents several limitations that future research should aim to address. One significant limitation is the methodology applied for the first objective of the research - textual semi-structured interviews coupled with thematic analysis - which was originally designed with human respondents in mind. This approach may not be fully appropriate for analyzing text generated by AI, as it may overlook nuances specific to AI-generated discourse. Therefore, there is a need for methodologies tailored specifically to AI-generated text analysis. Another point to consider is the recent launch of GPT-4, which boasts 500 times more parameters than its predecessor, suggesting potential shifts in AI capabilities that were not accounted for in this study. Additionally, conducting interviews at a single point in time does not account for the AI's evolving learning mechanisms. To gain a deeper understanding of AI-mediated brand evaluation, it would be beneficial to perform analyses at multiple intervals in a longitudinal study. To build on this research, future studies could apply our methodology to GPT-4 to assess any changes in brand personality evaluations within the automotive industry. Finally, future research should consider the perceived intentionality behind ChatGPT's responses, evaluating how the AI addresses commonplace brand-related questions across various industries and regions. This would help clarify the impact of AI on the consumer-brand dynamic and on brand personality as perceived through AI interactions.

Further research should expand the research on consumers and their interaction with ChatGPT. Researchers could explore how consumers connect with the AI platform for branding purposes and understand the most frequent inquiries that they pose. Then, investigating whether consumers use the AI platform during the decision-making process or for post-purchase inquiries and services will contribute to understanding ChatGPT's role in consumer-brand interactions. Future studies can also examine the perceived intentionality of ChatGPT in the context of the human-object relationship by exploring how ChatGPT responds to users' trivial queries about brands in different industries and geographical locations.

Managerial implications. The findings presented in the dataset contribute to the limited academic literature on the newly introduced AI platform and develop valuable insights that brands should consider when managing their online brand personality (Dwivedi et al., 2023; Paul et al., 2023; Teubner et al., 2023; Tsigaris & Teixeira da Silva, 2023). For instance, important themes related to brand personality are completely or partially absent from ChatGPT's outcomes. Themes such as environmentally sustainable strategies, proprietary connections, and extended luxury brands, are not fully considered by the AI platform in its evaluation. Of particular significance is sustainability given the future introduction of new typologies of engines in the market and more restrictive governmental regulations for automotive production. Also, interconnections between umbrella brands and brand extensions are not adequately included in ChatGPT's brand evaluations despite the significant investments in brand development and equity.

Furthermore, this investigation reveals substantial similarities between heterogenous brands, and, even if the scale width is limited, shows potential cases of misalignment between the conveyed and real brand personalities. In addition, ChatGPT has the potential to enhance the brand's personality by providing a personalized and consistent communication experience that reflects the desired traits. Companies should be nonetheless careful to ensure that the platform optimizes the overall customer experience creating no frustration or confusion, and that the conveyed traits are aligned with those of the brand. Recognizing ChatGPT's potential of showing human-like attitudes, such as perceiving and categorizing brands, has significant theoretical and practical implications because it profoundly influences the possible development of the relationship between humans and this AI platform. For instance, this understanding can lead to more effective human-AI conversations by taking into consideration the specific attributes of the individuals involved. Tailoring messages to comply with the psycho-social profile of the recipient (Carfora et al., 2020) can result in a more human-like performance (Kumar et al., 2022). In addition, understanding the mechanisms by which these perceptions are processed can advance theory and practices in consumer psychology and brand management.

Another important factor to consider is the integration of ChatGPT with other touchpoints. ChatGPT can improve the brand's personality by providing a consistent message across different touchpoints. By using ChatGPT in various channels, such as social media, email, and chatbots, brands can establish a cohesive brand voice and tone that reflects the desired personality traits. Consistency in brand communication can improve brand recognition and reinforce the brand's identity in the consumers' minds (Veloutsou, 2023). If the brand communicates its personality through different media, ChatGPT should be an integral part of the strategy and reflect the personality consistently. If ChatGPT is poorly designed or implemented, it can undermine brand perceptions rather than bolster them. ChatGPT's brand perception can also impact the reputation of the brands employing the model for customer interactions. A positive perception of the brand by ChatGPT can improve the brand equity, conversely, negative or misaligned perceptions can jeopardize long-term brand management efforts. As a result, practitioners in the automotive industry should integrate ChatGPT with other

touchpoints to ensure consistency in brand communication and establish a cohesive brand voice and tone that aligns with the desired personality traits.

Moreover, companies should pay attention to the data sources where ChatGPT gathers information on brand personality and should manage them consistently. An inherent risk associated with ChatGPT and its sources is the dissemination of misinformation (Dwivedi et al., 2023; Huh et al., 2023; Paul et al., 2023; Ray, 2023; Teubner et al., 2023). If the data source is inaccurate or misleading, ChatGPT can generate content that perpetuates false information and distorted perceptions. This circumstance can be particularly problematic when the generated text is shared on social media or other media platforms. If ChatGPT conveys a brand personality that is not aligned with the real one, brands can be portrayed through inaccurate and misleading information and consumers can receive responses that diverge from the intentions and communication efforts of the brand managers. As a consequence, brand strategies that include ChatGPT as a relevant touchpoint reduce the probability of misrepresentation by the AI platform.

According to Lemon and Verhoef (2016), touchpoints encompass all the points of contact between a customer and a company, including physical, human, and technological interactions. ChatGPT serves as a technological touchpoint because it offers customers a digital method of interacting with a company. As a touchpoint, ChatGPT has the potential to enhance the customer experience by providing a convenient and efficient means of communication. Customers can use ChatGPT to ask questions, report issues, or receive personalized recommendations without the need for physical visits or human intermediaries. The efficacy of ChatGPT as a touchpoint however depends on ChatGPT's perceptions of the brand. If ChatGPT fails to convey the brand personality accurately, it can create frustration for customers, and jeopardize both the overall customer experience and the brand equity. As a result, practitioners within the automotive industry should ensure ChatGPT's alignment with the real brand personality because inaccurate information can undermine the brand strategy. ChatGPT can enhance the customer experience as a technological touchpoint, however, its efficacy depends on its perception of the brand. In summary, this study elucidates ChatGPT's adeptness at appraising and differentiating brand personalities within the automotive industry, substantiating its analytical prowess against Aaker's established framework. As the automotive industry evolves, this research points to future directions that include adopting AI to convey and reinforce brand personality and exploring consumer interactions with AI platforms like ChatGPT, to fully leverage their potential in shaping and reinforcing brand perceptions in the digital age.

Originality of the paper. The research explores ChatGPT's ability to perceive brand-specific perceptions in the automotive industry. The findings of the research confirm its capability to discern brand personality, categorize brands according to Aaker's framework, and assign corresponding scores to indicators. This makes a significant contribution to the AI-driven branding literature and addresses a gap in understanding the platform's role in brand management. This study offers valuable insights to practitioners in branding strategies. ChatGPT's has the potential to anthropomorphize due to its human-like conversational abilities, impacting brand perceptions. It advocates for aligning ChatGPT's communication with desired brand personalities and maintaining consistency across various touchpoints, such as social media and email, to enhance brand recognition. It underscores the integration of ChatGPT with other touchpoints for a cohesive brand voice to highlight the impact on brand perceptions and equity. Despite ChatGPT's potential to improve customer experience, the study warns against the risk of misinformation from inaccurate data sources, emphasizing the need for consistent data management to prevent misrepresentation. In particular, the findings offer suggestions to the practitioners in the automotive industry, who should constantly monitor the platform and strive to include environmentally sustainable strategies and brand interconnections in ChatGPT's evaluations, which are essential for the evolving automotive landscape. Acknowledging methodological limitations, the study proposes refining analysis methodologies for AI-generated text. It anticipates improvements with ChatGPT4 and calls for future research to examine brand evaluations with the new version, employing a longitudinal approach to understand evolving responses.

Understanding the potentialities of metaverse for marketers. Insights from Italy

ANNARITA SORRENTINO¹ MICHELE SIMONI² LUCA VENTURINI³ MYRIAM CARATU⁴

Abstract

The current study presents an empirical analysis of the metaverse, contributing to the initial literature on this topic. Specifically, the research examines the implications and potential of the metaverse for both consumers and firms by investigating its impact on marketing opportunities. The research aim is achieved through a qualitative analysis. A case study approach was used to explore the practical opportunities related to using the Metaverse servicescape as a marketing enabler. Main results reveal the metaverse as an evolution of technologies (metatech) and the evolution of the experience environment (metascape). It also enriches the existing literature by offering an in-depth qualitative study in a context where scholars have mostly applied conceptual methods. Moreover, it proposes theoretical and practical implications that advance knowledge of the subject and offer ideas for future research and managers.

Key words: Metaverse; Metascape, Metatech; Qualitative analysis; Alterside

Framing of the research. *The rapid development of immersive technologies and metaverse applied to marketing has created new environments where consumers can find novel experiences to learn, enjoy, and escape, and firms may experiment with new ways to communicate their brand and achieve a more qualified audience (Batat, 2024; Ahn et al., 2022). The concept of the metaverse is not new (Stephenson, 1992); however, in the last two years, both academic (Barrera & Shah, 2023; Buhalis et al., 2023; Hajian et al., 2024; Taylor, 2022) and entrepreneurial attention has grown tremendously on this issue.*

From a theoretical point of view, research on the metaverse has intensified in recent months by trying primarily to codify a definition. Despite the general lack of consensus on the precise scope or definition of the metaverse and how it will evolve (Dwivedi et al., 2022), the term “metaverse”, a union of “meta” (beyond) and “verse” (short for “universe”), indicates a three-dimensional virtual world (Park & Kim, 2022): an immersive space within which individuals can move, share and interact through personalized avatars (Cunningham, 2014; Duan et al., 2021). The compound of “meta and “universe” concepts has also been utilized by (Choi & Kim, 2017) who define the metaverse as a space created by merging virtual reality and augmented reality with the real world. Barrera and Shah (2023) define Metaverse “as a technology-mediated network of scalable and potentially interoperable extended reality environments merging the physical and virtual realities to provide experiences characterized by their level of immersiveness, environmental fidelity, and sociability.” This definition of metaverse as a blend of different realities is reinforced by Siyaev and Jo (2021) and Ryskeldiev et al. (2018) who said that with the metaverse physical and digital objects co-exist and interact in live-time through mixed reality and by Buhalis et al. (2023) who specify that convergence of the physical with the digital in the metaverse experience will offer new opportunities to fascinate, involve, and keep consumers.

This study attempts to extend the metaverse management literature by conducting a novel empirical study that considers the metaverse from different perspectives. Firstly, Metaverse is a holistic immersive technology named metatech; Secondly, Metaverse is an experiential space for consumers in terms of a new way to learn, escape, entertain and for companies as a marketing enabler for brand experience, advertising, product placement, named metascape.

The metaverse has the potential to be a marketing enabler by supporting the creation of new forms of sponsorship, organic and paid advertising, product placement, and brand experiences that integrate with those already present in the physical world. Once the potential of the Metaverse as the next big communication channel has been identified, marketers should focus on successfully promoting products and services through it. The Metaverse platforms will present an ever-increasing number of immersive marketing tools designed to target specific demographic audiences as

⁴ e-mail: myriam.caratu@unint.eu

it establishes itself as a new 3D channel worthy of integration (Hollensen et al., 2022). Through Metaverse marketing, brands can communicate their brand universe to young consumers in digital spaces, increasing brand desirability and merging the online experience with the offline characteristics of the purchase. This can include physically touching the product to verify its quality, which has been shown to drive willingness to purchase even in augmented environments (Serravalle et al., 2022). However, selecting the right Metaverse platform and developing a marketing communication strategy without causing brand damage can be challenging due to the platform's developmental stage. Therefore, marketers should first identify their marketing objectives for entering the Metaverse and then choose the appropriate platform to promote their brands, products, or services. The goal of this study is to distinguish the concrete differences between the holistic experiences provided by current metaverse platforms, which will aid marketers in their decision-making process and assist scholars in defining their future research. According to Jooyoung Kim (2021), there will be a need to set an agenda for marketers and advertisers when the metaverse becomes massive populated. This is because the advertising models will differ from those of traditional mass media and will be more like the ads in video games. To comprehend the advertising models that will dominate the metaverse, it is crucial to first understand the motivations that drive users to enter it. These reasons are not solely economic, unlike those of advertisers. While the possibility of experiencing a virtual world of events and socializing is attractive to most consumers, the primary motivation remains the enjoyment of gaming. Numerous companies have recently entered the Metaverse as advertisers, including Nike and Disney. Their goal is to maintain a presence in the virtual world of consumers' 'second live'. These companies are aligning their marketing and communication strategies with the characteristics of the metaverse. They are creating immersive brand experiences that promote their ideas and values, while fostering a sense of community that transcends boundaries.

Purpose of the paper. We contribute to extant research by proposing an empirical study in an area where academics have mainly used theoretical approaches by providing a meaning of the metaverse and its current forms of use, as well as defining the trajectories that will characterize consumer experiences in the coming years. The results bring to light a metaverse that represents a "third dimension" where innovative technologies coexist, where the real merges with the virtual in the so-called "second life" and this produces interesting implications for companies and marketers. From a theoretical perspective, this study contributes to the marketing and management literature by integrating the characteristics of new technologies offered by the metaverse with the opportunities for marketing with empirical evidence which adds novelty to our research because literature can be compared with the point of view of entrepreneurs and experts. Managerial implications emerge that support the managers who want to understand what the development trajectories are and consequently how to take advantage of the metaverse's opportunities. This research extends the embryonic literature on metaverse by applying a two-step analysis, by revealing how the holistic technologies within the metaverse may create new opportunities for marketing.

Methodology. To provide a clear definition of the metaverse from a practical perspective, this study follows an empirical-based approach that excludes subjective evaluations and aims to understand the marketing opportunities related to the usage of these immersive platforms by conducting an in-depth qualitative analysis. Several semi-structured interviews were conducted with the first Italian marketing agency in the metaverse named 'Alterside'.

To achieve our research aim, we use the case study method as a research approach (Eisenhardt, 2020; Rashid et al., 2019) to understand the meaning of the metaverse and how it will change the paradigms of the consumer experience and the advertising opportunities for companies. Regarding the choice of the case, we respected the criteria of the research purpose.

Alterside is a marketing agency specializing in creating Virtual Reality, Augmented Reality and NFT experiences, services and content within the metaverse. The case study method is convenient when the form of the research question is "How?" (Yin, 2009). Because of the peculiarity of the case and the absence of a pre-existing theoretical framework, an exploratory research design was structured (Meredith, 1998; Yin, 2013); furthermore, we do not create propositions and hypotheses (Mills et al., 2009). The exploratory nature of case studies can also reveal new facets of the phenomenon under analysis (Dubois & Gadde, 2014; Eisenhardt & Graebner, 2007).

Through a qualitative research approach based on primary and secondary data, we used multiple sources of evidence for the triangulation of data (Yin, 2009), and we organized the case study analysis into two phases. We collected information from personal interviews and online documentation such as reports, statistical data, and specialized press articles. As a primary source of data, we conducted 10 interviews with the various actors involved in the company Alterside. Through a semi-structured questionnaire, we requested information on the main Alterside actors (the founder, the key account manager, the marketing manager, and the different project managers). The personal interviews comprised open-ended questions to collect the perceptions about the definition and meaning of metaverse and the current and future opportunities for advertisers. Each conversation typically took 60 minutes. All interviews were audio-recorded, transcribed verbatim to facilitate the analysis, and anonymized. As secondary sources, several media publications, and official reports from January 2023 to December 2023 were also analyzed to understand the state of the art of the metaverse. The analysis practiced an iterative and inductive approach. Inductive theory based on qualitative data is appropriate in an understudied empirical environment in which there is relatively little prior work (Bansal et al., 2018). The multiple data elements furnish a stronger demonstration and consistency of the key objectives of the case study. Although multiple sources of evidence (e.g., personal interviews and online documentation) are different and independent, their combination can be fundamental to scholars as complementary perspectives of the phenomenon may be produced. Therefore, personal interviews, official company data, media publications and other evidence were triangulated and analysed through a thematic analysis (Braun and Clarke, 2006).

Results. *In this paper, we try to enrich the marketing literature by talking about the metaverse, the metaverse has been framed as a new holistic consumption space where all the most innovative technologies (e.g. NFT, VR, AR, blockchain, cryptocurrencies) able to coexist to create a third dimension that adds to the physical and digital one.*

Indeed, the first interesting thing that emerged from our study is the holistic dimension of the metaverse, that brings all the emerging technologies together (AR and VR, NFT, blockchain, cryptocurrencies) to create what happens in reality in a virtual way. This phenomenon has been called the third dimension that will not replace the physical or digital life that you already live, but will add to it, creating more effectively usable opportunities in the metaverse and others more appropriate for real or digital life. According to Alterside, the metaverse is a new environment where some existing technologies coexist creating a new dimension of fruition, in addition to the offline and online one, the experience of a virtual second life.

Fig. 1 – The opportunities of metaverse for marketers

In this paper, the metaverse has been framed as a new holistic consumption space where all the most innovative technologies (e.g. NFT, VR, AR, blockchain, cryptocurrencies) able to coexist to create a third dimension that adds to the physical and digital one.

Indeed, the first interesting thing that emerged from our study is the holistic dimension of the metaverse, that brings all the emerging technologies together (AR and VR, NFT, blockchain, cryptocurrencies) to create what happens in reality in a virtual way. This phenomenon has been called third dimension that will not replace the physical or digital life that you already live, but will add to it, creating more effectively usable opportunities in the metaverse and others more appropriate for real or digital life.

As emerged from the results, going to the metaverse to buy a dress does not exclude that I will go shopping in stores, nor will I no longer go on e-commerce, the third dimension is halfway between the two. So, if today we are unconsciously used to living in these two dimensions online and offline, tomorrow we will live in three dimensions online and offline and in a hybrid one in between, which should unite what we do offline and what we do online, giving us a third way of interacting.

An interesting, emerged result is related to the opportunities for advertisers. Indeed, what we imagine today is that advertising in the metaverse will be much more like what we experience offline today. The difference is that advertising in physical space has limits. As an entrepreneur interviewed explained to us, you can put a billboard on the wall of a building and it ends up there, in the metaverse, however, you can put a billboard that changes according to the user who looks at it. The interesting thing is that in the metaverse a billboard becomes interactive, if there is a call to action, the avatar can touch it and continue the experience elsewhere, in another environment, for example, directly in a shop. Product placement will be used a lot as a form of advertising and the innovation will be that the user will be able to buy both the digital version of the avatar (the so-called digital twin) and the real one that arrives at home with the courier of that product and businesses they can measure the returns of that advertising because the behaviors are tracked by the data. This means that the metaverse opens a series of new opportunities for companies, still a bit skeptical today and waiting for the metaverse to become accessible. In fact, what will make these practices more concrete will be the diffusion of the metaverse experience among consumers and this will only happen when viewers spread in an accessible way.

Research limitations. *The paper contributes to the literature on the metaverse with an empirical exploration of the meaning and opportunities, by using a qualitative approach. Our study is a first attempt to explore the current state-of-art about the metaverse and for identifying some key aspects of its future implementation. Although this paper represents an important informative contribution for companies and academics, it should be emphasized that it is defocused on specific aspects that will certainly be the subject of a second research step.*

Future research may be conducted by interviewing firms that have already experienced service in the metaverse and, on the other hand, it could be also important to capture the consumers perceptions on the metaverse.

Managerial implications. Managerial implications emerge that support the managers who want to understand what the metaverse is and what the development trajectories are and consequently how to take advantage of the metaverse's opportunities. Our study has practical and academic implications in the field of technology applied to marketing. Our qualitative investigation incorporates both customer and company perspectives, thus increasing the understanding of the subject and providing meaningful contributions for marketers who want to investigate the mechanism of promotional strategies with reality-enhancing technologies (Hilken et al., 2022). From the firm's point of view, the identification of the meaning and the future development of the metaverse within a marketing strategy should be useful. The third dimension offered by the metaverse allows understanding that they will not replace the current marketing activities but rather it will represent an extra option where place the most appropriate brand experiences. The element of second life, from a marketing point of view, offers opportunities to recreate everything that exists in real life, in virtual, thus increasing sales opportunities for the so-called digital twin. Finally, the surprising finding that metaverse may perceive and keep the biometric data has important practical implications.

First, it makes it possible to monitor marketing actions also through perceived data, which is the most important in consumer purchasing behaviour. Furthermore, it gives the possibility of profiling consumers based on biometric variables and making advertising even less invasive than it is now in the two-dimensional internet.

Originality of the paper. We contribute to extant research by proposing an empirical study in an area where academics have mainly used theoretical approaches by providing a meaning of the metaverse and its current forms of use, as well as defining the trajectories that will characterize consumer experiences in the coming years. The results bring to light a metaverse that represents a "third dimension" where innovative technologies coexist, where the real merges with the virtual in the so-called "second life" and this produces interesting implications for companies, and marketers.

“The influence of individual values on purchase intention of fair-trade products: An analysis on Italian consumers”

NOHAILA KARTTI¹ GIUSEPPE FRANZESE² CHIARA CANNAVALE³

Abstract

This paper examines how individual values influence the purchase intentions of fair-trade products among Italian consumers. Fair-trade initiatives promote fair and sustainable practices, aiming to empower marginalized communities.

By focusing on consumers' individual values, this research seeks to uncover the underlying motivations driving fair-trade purchasing decisions. A survey-based methodology will be employed to explore consumers' values and the impact of values on fair-trade purchase intentions. Consumers' values will be investigated using the Schwartz value theory (1992).

Data will be collected using an online survey submitted to Italian consumers. The survey will be developed from sources already used and validated in the literature. An exploratory factor analysis (EFA) will be performed on the ten Schwartz metavalues measured using the portrait values questionnaire (PVQ) method. Also, a confirmatory factor analysis (CFA) will be performed to assess the psychometric properties of the scales. Finally, multiple regressions will be carried out to determine if there are significant associations between specific cultural values and the intention to buy fair-trade products. Research is ongoing, but early results suggest a positive effect between some individual values of (SVT) and intention to purchase fair-trade products, with implications for marketing strategies and policy making. The originality of this paper lies in its focus on Italian consumers and their individual values, contributing to a deeper understanding of fair-trade consumption patterns and promoting ethical and sustainable consumer behavior in the Italian market.

Keywords: *Schwartz value theory; individual value, fair-trade product; purchase intention; ethics of consumption*

Framing of the research. *The tension connected to globalization and the focus on profitability and efficiency have limited the development of fair-trade between manufacturers and retailers (Fiedoruk, 2021), and small-scale producers and labourers frequently struggle to strengthen their negotiating position in both local and international markets (Ncube, 2020). Fair-trade organisations (FTOs) promote different business relationships with farmers and craftsmen in developing countries and rural regions that frequently experience social and economic marginalization to alleviate this gap (Krier, 2006). These collaborations emphasize sustainable environmental practices, safe working conditions, and fair compensation to empower underprivileged communities and promote fair-trade practices. Therefore, creating sustainable and people-centred business models is the main goal of fair-trade (FT) practices (Bhavsar et al., 2021). Hence, fair-trade could be considered as an alternative to international conventional trade. It is a kind of trading partnership that promotes marginalized or disadvantaged producers through sustainable development (Śliwińska, 2023).*

The promotion of fair trade chains becomes even more critical when considering policymakers' global social and environmental sustainability goals. In particular, delving deeper into issues related to fair-trade products could help achieve some of the goals outlined in the 2030 agenda concerning the 17 Sustainable Development Goals (SDGs) defined by the United Nations. Specifically, these goals include points 1 (No poverty), 8 (Decent work and economic growth), and 16 (Peace, justice, and strong institutions).

From this standpoint, fair-trade provides consumers with a variety of products that adhere to elevated social and ecological criteria (Sellare et al., 2020), aligning with the increasing consumers' awareness of the environmental and social impacts of their purchasing decisions. The consumer's desire to address social injustices and inequality while aiding firms in their “transition away” from the conventional, unsustainable economic model is reflected in this tendency (White et al., 2019; Ethical Consumer, 2021). Based on these considerations, understanding and analyzing the factors that most influence consumers' purchase intentions of fair-trade products can be important for fair-trade firms, NGOs
