## Supplement 1. Additional tables and figures

Table S1 - Data on the analysed specimens. The table shows the sampling area and individual codes as well as the identification of individuals based on morphological characters, nuclear and mitochondrial results. $\mathrm{RP}=$ Raja polystigma, RM = Raja montagui. See Excel file at www.int-res.com/articles/suppl/ m554p099_supp.xlsx

Table S2 - PCR conditions for the 7 microsatellite loci by El Nagar et al. (2010) optimized for the locus amplification in Raja polystigma and $R$. montagui
$\left.\begin{array}{llllll}\hline \text { Locus } & \begin{array}{l}\text { Fluorescent } \\ \text { Label }\end{array} & \begin{array}{l}\text { Accession } \\ \text { Number }\end{array} & \text { Primers (5'-3') } & \begin{array}{l}\text { Core } \\ \text { sequence }\end{array} & \mathrm{Ta}\left({ }^{\circ} \mathrm{C}\right) \\ \hline \text { LERI24 } & \text { TET } & \text { CV221951 } & \begin{array}{l}\text { F: GCACGTACGCAGAATTTGAA } \\ \text { R: CCGGCACGTGTAATTTAAGG }\end{array} & \text { (TC) } 8 & 52 \\ \text { LERI26 } & \text { TET } & \text { CV068031 } & \begin{array}{l}\text { F: GGAGCAGCAGTGAGGACAAT } \\ \text { R: CTCCTACCGTCATGCCTCAT }\end{array} & \text { (GA)12 } & 48 \\ \text { LERI27 } & \text { TET } & \text { CV068389 } & \begin{array}{l}\text { F: AACTGGGCAACTGACCACA } \\ \text { R: AACGTTCTGGGTGCTGCTAC }\end{array} & \text { (CT)15 } & 54 \\ \text { LERI34 } & \text { HEX } & \text { CO050073 } & \begin{array}{l}\text { F: CTTGCAATCTTTTGCCGAGT } \\ \text { R: GTTCATCGGCCTCTTGATGT }\end{array} & \text { (GT)11 } & 52 \\ \text { LERI44 } & \text { FAM } & \text { EE991287 } & \begin{array}{l}\text { F: CAGCGAGTAAACACCGACCT } \\ \text { R: TGCGATGATCTTGAAAGACG }\end{array} & \text { (GT)11 } & 56 \\ \text { LERI50 } & \text { FAM } & \text { DR713467 } & \begin{array}{l}\text { F: AATAATTGTGCCTCTTTGAGACAT } \\ \text { R: CACAGGGAACGCAATACCTT } \\ \text { LERI63 }\end{array} & \text { FAM } & \text { CV221951 } \\ \text { F: TTTTGATCGGCTGCAAAAAT } \\ \text { R: CGGACTGTATAATGTGTACCAACC }\end{array}\right)$

Table S3 - Summary statistics of the microsatellite dataset. A= number of alleles, Ar= allelic richness, Ho= observed heterozygosity, $\mathrm{He}=$ expected heterozygosity, $\mathrm{NA}=$ estimate of null allele frequency. $\mathrm{HWE}=$ test of deviation from HW equilibrium $*=\mathrm{P}<0.05, * *=\mathrm{P}<0.01, * * *=\mathrm{P}<0.001$. Codes of population samples are given as in Table 1.

Table S4 - Detailed results of the analyses performed to assess evidence of hybridization/introgression between Raja polystigma and R.montagui. Table S4A defines the assignment criteria, while Table S4B details the results obtained for each individual. See Excel file at www.int-res.com/articles/suppl/ m554p099_supp.xlsx

Table S5-Mean genetic distances (expressed as F-statistics indexes and estimated by AMOVA) between $R$. polystigma and $R$. montagui $(\mathrm{A})$ and within R.polystigma $(\mathrm{B})$ at the mitochondrial gene fragments and microsatellites.

| Comparison/Markers | \% variation | F statistics | P value |
| :---: | :---: | :---: | :---: |
| A: Two groups ( $R$. montagui vs $R$.polystigma) |  |  |  |
|  |  |  |  |

Fig. S2 - Principal Coordinates Analysis (PCoA) of the Raja polystigma and R. montagui population samples. Scatter plots built on the first two principal coordinates (coordinate 1, x axis; coordinate 2, y axis) based on the nucleotide variation at markers COI (Fig. S2A), CR (Fig. S2B) and 16S (Fig. S2C). Codes of population samples are given as in Table 1. The barplot of Eigenvalues of the first and second coordinates and the stress coefficient (d) are reported in each PCoA graph.

Fig. S3 - Bayesian Skyline Plots showing changes in the female effective population sizes $\left(\mathrm{N}_{\mathrm{ef}} \mu\right)$ during time (MYA=million years ago). Black lines represent the median estimates of $\mathrm{N}_{\mathrm{ef}} \mu$, while grey lines the upper and the lower $95 \%$ highest posterior density (HPD) limits.

## Supplement 2. Molecular protocols and data analysis methods

## PCR conditions optimized for the amplification of loci in Raja polystigma and R. montagui

All PCR reactions were performed in either a Personal or a T-Gradient thermocycler (Biometra). The PCR reactions of COI and 16 S gene fragments were carried out in a total volume of $50 \mu \mathrm{~L}$ containing $5 \mu \mathrm{~L}$ of template DNA ( $\sim 40 \mathrm{ng}$ ), $5 \mu \mathrm{~L}$ of 10 X reaction buffer (Invitrogen), $4 \mu \mathrm{~L}$ of 10 mM dNTP mixture, $2.5 \mu \mathrm{~L}$ of each 10 mM primer, $3 \mu \mathrm{~L}$ of $50 \mathrm{mM} \mathrm{MgCl}_{2}$, and 1.25 U recombinant Taq polymerase (Invitrogen). The temperature profile included an initial denaturation at $94^{\circ} \mathrm{C}$ for 3 min , followed by 34 cycles of denaturation at $94^{\circ} \mathrm{C}$ for 30 s , annealing at $54^{\circ} \mathrm{C}$ for 30 s , elongation at $72^{\circ} \mathrm{C}$ for 1 min , and a final elongation step at $72^{\circ} \mathrm{C}$ for 7 min . The thermal profile for the CR amplification was as in Valsecchi et al. (2005).

The PCR reactions of the microsatellite loci were carried out in a total volume of $10 \mu \mathrm{~L}$ containing $1-3 \mu \mathrm{~L}$ of DNA template ( $\sim 10 \mathrm{ng}$ ), $1 \mu \mathrm{~L}$ of 10 x reaction buffer, $0.8 \mu \mathrm{~L}$ of 10 mM dNTP mixture, $0.5 \mu \mathrm{~L}$ of each 10 mM primer (the forward primer was fluorescent labeled), $0.5 \mu \mathrm{~L}$ of 50 mM MgCl 2 and 0.25 U of recombinant Taq polymerase (Invitrogen). The temperature profile was an initial denaturation step at $94^{\circ} \mathrm{C}$ for 3 min , followed by 30 cycles of denaturation at $94^{\circ} \mathrm{C}$ for 30 s , annealing at $48-56^{\circ} \mathrm{C}$ for 30 s , elongation at $72^{\circ} \mathrm{C}$ for 30 s . The final elongation was at $72^{\circ} \mathrm{C}$ for 10 min .

## Clustering of individuals and hybridization analyses

The Bayesian clustering analyses was performed using STRUCTURE 2.3.4 (Pritchard et al. 2000, Hubisz et al. 2009) and a stepwise approach with three tests. The Testl was carried out assuming an admixture ancestry model with the geographical origin of samples as prior information (LOCPRIOR models), associated with a correlated allele frequencies model. For each simulation of K (1-10), five independent replicates were run, setting a burn-in period of 250,000 iterations and $1,000,000$ iterations for the MCMC. The true $K$ was inferred using Evanno's $\Delta k$ and Pritchard's average log probability methods (Pritchard et al. 2000, Evanno et al. 2005), both implemented in the STRUCTURE HARVESTER v.0.6.93 web application (Earl \& Von Holdt 2012). Once the most likely number of clusters was selected, a supplemental run was performed with the same settings for additional ten independent replicates at the selected K .
The Test2 was carried out with the same settings and priors of the first test but also adding the population of origin of selected individuals as prior to assist ancestry estimation for the other individuals, applying the PFROMPOPFLAGONLY option. In this way, it was possible to update the allele frequencies, $P$, using only a pre-specified subset of the individuals to be regarded as the "reference" set (pre- assigned POPFLAG $=1$ ), chosen on the basis of both the results of the first test and the species-specific mtDNA haplotype. Applying a good balance between power and accuracy, as defined in simulations trials using HYBRIDLAB v1.0 (data not shown, Nielsen et al. 2006), a $\mathrm{Q} \geq 0.90$ was set as threshold. Each individual with a proportion of membership $\mathrm{Q} \geq 0.90$ and $95 \%$ of Credible Interval (CI) falling within the range $0.8-1.0$ was considered as a purebred (Negri et al. 2013), while individuals with $\mathrm{Q}<0.90$ but $\mathrm{Q} \geq 0.80$ were considered as putative purebred. Hybrid/admixed individuals were classified as those with assignment probabilities between $50 \%$ and $80 \%$. Finally, it was considered as unclassifiable any individual whose Q value may have indicated hybridization/admixture but the credibility intervals included values 1.00 , and/or the credible intervals for two categories overlapped irrespectively from its Q (see details Table S4). The Q and CI values were obtained as the mean values from ten independent runs with $\mathrm{K}=2$, using the same settings as in the first test.

The Test3 used priors to test for migrant or hybrid/introgressed individuals. By defining the population of origin as prior for all individuals, this pre-defined groups info was used for evaluating whether any individuals in the sample were immigrants to their supposed populations, or have recent immigrant ancestors. The input file was built by setting POPFLAG $=1$ for all individuals, asking the program to test whether each individual had an immigrant ancestor in the last two generations (GENSBACK $=2$ ).These latter settings inferred the posterior probability of individuals being correctly assigned to the a priori defined population, and the probability of having ancestry in the other population (i.e. in the other species). As recommended by the authors, the MIGRPRIOR value, indicated as $v$ in (Pritchard et al. 2000), was set to 0.05 to allow for some misclassification. The Q values were the mean values derived from ten independent runs with $K=2$ with settings as in the first test.
An additional Test4 was realized with NEWHYBRIDS (Anderson \& Thompson 2002) to infer estimates of admixture proportions and hybrids ancestry. This software calculates Bayesian posterior probabilities (qn) that individuals fall within particular user-defined hybrid categories (purebred, F1, F2, backcross, etc.) based
on the genotypic information. The analyses were performed specifying prior information on reference, purebred R. montagui and R. polystigma individuals (as defined in the STRUCTURE Test2) by means of the " $z$ " option in the NEWHYBRIDS input file. Model priors were set to "Jeffreys-like" for both the mixing proportions and the allele frequencies. For all individuals, probabilities of belonging to four (purebred 1, purebred 2, F1 and F2) genotype frequency classes were estimated. All results were based on $50,000 \mathrm{MCMC}$ sweeps following a burn-in period of 50,000 , with ten independent replicates for each series.

## Mitochondrial polymorphism analysis

Sequences were checked and edited with the software MEGA6 (Tamura et al. 2013).
The number of haplotypes $\left(\mathrm{N}_{\mathrm{h}}\right)$ and the haplotype (h) and nucleotide diversity ( $\pi$ ) (Nei 1987) were estimated using DNAsp v. 5 (Librado \& Rozas 2009). Mean interspecific sequence divergence was calculated with MEGA 6 (Tamura et al. 2013), after the complete deletion of all ambiguous positions for each pair of sequences, as the between-species mean p-distance.

## Haplotype trees

The relationships among haplotypes were investigated with Bayesian and Maximum Likelihood approaches using MrBayes v 3.1 (Huelsenbeck and Ronquist, 2001; Ronquist and Huelsenbeck, 2003) and PhyML v3.0 (Guindon et al., 2010), respectively. In MrBayes the analyses were performed using two parallel runs of 2 million generations each, using four chains, sampling every 100 generations, burnin 0.25 , and saving branch lengths. The performance of the analyses was evaluated using the software Tracer 1.6 (Rambaut et al., 2014). Maximum-likelihood (ML) analyses of the mtDNA were performed in PhyML under 100 replications, using the best fit model the data identified by JModelTest v2. Trees were visualized with MEGA (Figure S1).

## Species and pairwise population differentiation

The genetic differentiation among the putative species and population samples (pairwise $\mathrm{F}_{\mathrm{st}} \mathrm{s}$ ) were computed using the substitution model of Tamura (Tamura 1992). This is the closest model implemented in Arlequin to the optimal evolutionary model HKY (Hasegawa et al. 1985) selected by the software JModelTest v2 (Darriba et al. 2012) based on the Bayesian Information Criterion (BIC).

Statistical significance $(\alpha=0.05)$ of overall and pairwise F-statistics values was obtained after 10,000 permutations and adjusted using false discovery rate (FDR) correction for multiple comparisons using the method of Benjamini \& Hochberg as implemented in SGOF+ (Carvajal-Rodriguez \& de Uña-Alvarez 2011).

## Principal coordinate analysis

Pairwise $\Phi$ sts between population samples were transformed into Euclidean matrices through the addition of smallest positive constant (Cailliez 1983), and used to reconstruct scatter plots of Principal Coordinates Analysis (PCoA) using the packages ade4 (Dray \& Dufour 2007) and ape (Paradis et al. 2004) in R environment 3.0.2 (R-Core-Team 2013).

## Demographic analyses

Bayesian skyline plot (Drummond et al. 2005) was obtained in BEAST 1.75 (Drummond \& Rambaut 2007) using a strict molecular clock and a mutation rate of $0.005 /$ million years (Chevolot et al. 2006b), and the optimal model of nucleotide evolution (HKY) selected with JModelTest. We performed a Markov Chain Monte Carlo (MCMC) run of $50,000,000$ generations sampled every 5,000 generations with the first $10 \%$ of the sampled points removed as burn-in. The quality of the run was assessed by effective sample size (ESS) > 200 for each parameter using Tracer 1.6 (Rambaut et al., 2014). The same software was used to produce the skyline plots.
