### Just Accepted

“Just Accepted” manuscripts have been peer-reviewed and accepted for publication. They are posted online prior to technical editing, formatting for publication and author proofing. The American Chemical Society provides “Just Accepted” as a service to the research community to expedite the dissemination of scientific material as soon as possible after acceptance. “Just Accepted” manuscripts appear in full in PDF format accompanied by an HTML abstract. “Just Accepted” manuscripts have been fully peer reviewed, but should not be considered the official version of record. They are citable by the Digital Object Identifier (DOI®). “Just Accepted” is an optional service offered to authors. Therefore, the “Just Accepted” Web site may not include all articles that will be published in the journal. After a manuscript is technically edited and formatted, it will be removed from the “Just Accepted” Web site and published as an ASAP article. Note that technical editing may introduce minor changes to the manuscript text and/or graphics which could affect content, and all legal disclaimers and ethical guidelines that apply to the journal pertain. ACS cannot be held responsible for errors or consequences arising from the use of information contained in these “Just Accepted” manuscripts.

This document is the unedited Author's version of a Submitted Work that was subsequently accepted for publication in ACS Sustainable Chemistry & Engineering copyright © 2018 American Chemical Society after peer review.

To access the final edited and published work see <https://pubs.acs.org/doi/10.1021/acssuschemeng.8b04983>.

KEYWORDS. Hydrometallurgy; WPCBs; Noble metals; Recycling; Green Chemistry;

Iodine.

ABSTRACT. An extensive investigation on the NMs content in different classes of

WPCBs (Random Access Memories, RAMs; Network Interface Controllers, NICs;

motherboards; TV, DVD/CD player, hard-drive and mobile phone PCBs) has been

performed to define the most appropriate case study and provide a robust database

1  
2  
3 useful for workers in the waste valorisation field. Following accurate selection,  
4  
5  
6  
7 mechanical comminution, representative sampling, quantitative digestion and analytical  
8  
9  
10 characterization (ICP-AES), RAMs and mobile phone PCBs confirmed to be the  
11  
12  
13 “richest” source, while TV PCBs the “poorest” one in term of NM content. Accordingly  
14  
15  
16  
17 the RAMs case study has been employed for the application of a new Noble Metals  
18  
19  
20 (NMs) recovery method, previously set-up on finely comminuted WEEE underwent  
21  
22  
23 materials enrichment by mechanical separation. Despite the very large amount of  
24  
25  
26  
27 vitreous-plastic and metallic materials present in the mixture, satisfactory NMs recovery  
28  
29  
30 yields (Cu 70%, Ag 92%, Au 64%) with limited by-products formation have been  
31  
32  
33  
34 obtained using safe and recyclable reagents in mild conditions: citric acid for base  
35  
36  
37 metal leaching; ammonia in oxidizing environment for Cu and Ag separation and  
38  
39  
40 recovery; triiodide aqueous solution for gold recovery; room pressure; 25-100°C. The  
41  
42  
43  
44 reported results provide useful quantitative parameters for assessing the profitability of  
45  
46  
47  
48 an industrial scale-up of the new sustainable NMs recovery method.

## Introduction

One of the great modern-days challenges of our society is to give a “new life” to the obsolete goods which are destined to landfill if not differently managed. Today, regulations from several governments world-wide, addressed to face the concern of waste accumulation and Earth-planet pollution, encourage a more environmentally respectful waste management and the preservation of natural reserves of raw materials through secondary raw materials enhancement and sustainable reclamation processes in a *circular economy* vision.<sup>1,2,3,4</sup> Waste Electric and Electronic Equipments (WEEE) are the object of a specific attention in that sense, due to the amount of waste generated by year (with a  $\geq 5\%$  growth by year, it has been recognized as the fastest growing waste stream in the world)<sup>5</sup> and the consequent drawbacks of their disposal.<sup>6</sup> Indeed, the production of modern electronics involve the use of both hazardous and “critical” materials,<sup>7</sup> among them a great deal of scarce and expensive resources (e.g. around 10% of total gold worldwide is used for their production). This represents an environmental concern, thinking on the related pollution and human health risks they

1  
2  
3 can generate and on the depletion of limited raw materials. At the same time, it may be  
4  
5  
6  
7 turned into a value when the end-of-life goods are reprocessed to enhance the  
8  
9  
10 materials they are constituted off. A great interest in metals recovery is growing up  
11  
12  
13 worldwide at industrial and research level and it is demonstrated by the numerous and  
14  
15  
16 increasing conventions and research papers on this topic in the last five years.<sup>8-11</sup>  
17  
18  
19

20  
21 Among WEEE, Waste Printed Circuit Boards (WPCBs) are the most intriguing and  
22  
23  
24 challenging source of valuable raw materials because of their qualitative and  
25  
26  
27 quantitative metal composition. Thus, in the last decades they were recognized and  
28  
29  
30 named as “urban mines”, because the amount of precious and “critical” metals they  
31  
32  
33 contain, often larger than in their ores.<sup>12,13,14,15,16</sup> In this context, Noble Metals (NMs)  
34  
35  
36 play a crucial role in materials recovery due to their peculiar properties and for their high  
37  
38  
39 economical value which often represents the economical *driving force* to make the  
40  
41  
42 whole recovery process affordable. Gold, silver, palladium and copper are the most  
43  
44  
45 widely employed valuable metals in PCBs manufacturing. They combine high electrical  
46  
47  
48 and thermal conductivity with high resistance to the oxidation. These features, coupled  
49  
50  
51 with their malleability and ductility, make these materials particularly appealing for  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 industrial application as conductors in long lasting high technologies.<sup>17</sup> Gold, the noblest  
4  
5  
6  
7 one, is widely used as an external metallization in electrical contacts where high  
8  
9  
10 reliability is required and can be appreciably found in PCBs, but also in Central  
11  
12  
13 Processing Units (CPU), printer cartridges, and sim and smart cards. Silver, the most

59  
60

industrial application as conductors in long lasting high technologies.<sup>17</sup> Gold, the noblest one, is widely used as an external metallization in electrical contacts where high reliability is required and can be appreciably found in PCBs, but also in Central Processing Units (CPU), printer cartridges, and sim and smart cards. Silver, the most conductive among metals, is often used in PCBs as solder alloy or paste but its most peculiar role is in creating electrical pathways and high sensitive silver membrane switches. Palladium can be used as an alternative plating material to gold, or used in small amount in conductive tracks in hybrid integrated circuits (HIC) often paired with silver, but its most important application in PCBs is in multi-layer ceramic capacitors (MLCC). Copper, the most massively NM employed in PCBs, is widely used for circuit pathways, magnetic induction coils and windings, contacts and connections. Platinum and other Platinum Group Metals (PGMs; primarily Ir, Rh) are used as well in some extent, mainly in electrode coatings and fiberglass. They are also used in EEE for liquid crystals, flat-panel displays and cathode ray tubes manufacture. Despite the industrial interest and growing recovering rates, NMs are still scarcely recovered<sup>18,19,20</sup> and the recovery is mainly performed by conventional, often energy and environmentally

1  
2  
3 demanding, processes inherited by ore mining.<sup>20</sup> Typically, companies working in the  
4  
5  
6 field of NMs production and/or treatment by means of conventional methods, adapted  
7  
8  
9 their industrial process to the recovery purposes. The most diffused industrial practices  
10  
11  
12 for NMs recovery from WPCBs are based on pyrolysis and electrolysis.<sup>21</sup>  
13  
14  
15  
16 Hydrometallurgical methods are industrially applied as well, but the widespread of their  
17  
18  
19 application is limited by the use of harmful reagents (i.e. cyanidation and aqua-regia  
20  
21  
22 leaching) and by the heterogeneous and composite composition of the scraps which  
23  
24  
25  
26 makes the process poorly effective and selective.<sup>21,12</sup> The high costs and, often,  
27  
28  
29 harmfulness of the recovering processes, heavily discourage new actors interested in  
30  
31  
32 this field to entry into the market. Nevertheless more sustainable NMs recovery from  
33  
34  
35 complex matrix such as WPCBs is a very challenging issue not satisfactorily solved yet.  
36  
37  
38  
39 In this context, new hydrometallurgical methods recently set-up on lab or pilot scale,  
40  
41  
42  
43 seem to give a promising contribution for designing new industrial plants able to  
44  
45  
46  
47 combine effectiveness and low environmental impact accordingly to *green chemistry &*  
48  
49  
50  
51 *engineering principles*.<sup>17</sup> Among them, we found high effectiveness and selectivity, in  
52  
53  
54  
55 high purity NMs recovery by using benign, selective and recyclable reagents in very  
56  
57  
58  
59  
60

1  
2  
3 mild conditions from a mixed metallic fraction of WEEE obtained by means of shredding  
4  
5  
6  
7 and electrostatic and magnetic separation techniques.<sup>22</sup> This method consists of a  
8  
9  
10 sequence of steps involving the selective leaching of the different metals from the  
11  
12  
13 comminuted sample by using: (1) a refluxing aqueous citric acid solution able to  
14  
15  
16 dissolve Sn, Zn, Pb, Ni, and other base metals; (2)  $\text{NH}_3$  in combination with an  $\text{IO}_3^-/\text{I}^-$   
17  
18  
19 mixture allowing either the oxidation of Cu and Ag, and their separation by selective AgI  
20  
21  
22 precipitation; (3) an  $\text{I}^-/\text{I}_2$  mixture able of leaching quantitatively Au metal from the solid  
23  
24  
25 residue. Each step is followed by a further treatment, typically a chemical or  
26  
27  
28 electrochemical reduction, for obtaining high-rate metal and reagent recovery. The  
29  
30  
31 “chameleon” behavior of iodine, which shows versatile redox/complexing/precipitating  
32  
33  
34 capabilities, allows one to achieve the selective NM leaching and the reagent and metal  
35  
36  
37 recovery, towards a potentially “zero waste” process. Nevertheless the very  
38  
39  
40 heterogeneous composition of WEEE and the inefficiency of commercial mechanical  
41  
42  
43 pre-treatments plants, in terms of loss of valuable materials during the shredding and  
44  
45  
46 separation phases and their cost, still limit the industrial application of sustainable NMs  
47  
48  
49 recovery methods. It is worth noting that the number of companies able to produce a  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 coarse comminuted WPCBs material on their own is greatly increasing, while just few of  
4  
5  
6  
7 them are currently able to produce good quality enriched metallic fractions obtained as  
8  
9  
10 the output of a selective mechanical separation process. On these basis, the recent  
11  
12  
13 project #Recovery #Green #Metal, involving Italian companies operating in WEEE  
14  
15  
16 management, is addressed to face specific, still open, scientific and technological  
17  
18  
19 issues which affect the robustness (applicability on a wide range of different materials),  
20  
21  
22 the sustainability (environmental but also technological and economical) and scalability  
23  
24  
25 (applicability on a different scale) of the process, in order to assess the potential  
26  
27  
28 profitability and promote the technology transfer of the proposed recovering method.  
29  
30  
31

32  
33  
34 Here we report the results of an important part of this study involving: i) the accurate  
35  
36  
37 gold, silver, palladium and copper characterization by means of quantitative chemical  
38  
39  
40 analysis, by a selection of WPCBs samples underwent combined mechanical  
41  
42  
43 (shredding) and chemical (leaching) processes, in order to build a robust database  
44  
45  
46 functional to this work and useful as a reference for researchers and companies  
47  
48  
49 interested in waste valorisation; and, as a case study, ii) the preliminary results on the  
50  
51  
52 application of our sustainable NMs recovery process on a shredded sample of Random  
53  
54

## 27 **Materials and methods**

28  
29  
30  
31  
32 Reagents and solvents for chemical digestion, characterization and leaching of the  
33  
34  
35 samples, were purchased from Sigma-Aldrich (except citric acid anhydrous FU-E 330  
36  
37  
38 from ACEF, Italy) and used without further purification. WPCBs of different origin were  
39  
40  
41  
42 supplied by companies (see acknowledgments).  
43  
44

### 45 **WPCBs comminution and characterization**

46  
47  
48  
49 **Comminution** The size-reduction of WPCBs was performed by the STIIMA-CNR De-  
50  
51  
52 manufacturing Pilot Plant – Cell 3 – Mechanical Recycling, under dry conditions in two  
53  
54

60

different stages after the removal of some minor components (i.e. motor and rotating supports, fasteners and ferrous parts) not containing NMs. A preliminary comminution was performed with a single shaft shredder Erdwich M600/1-400. The output product of this preliminary size-reduction (10 mm) was thus subjected to a further shredding process with cutting mill (rotor speed: 1500 rpm), adopting grates of 2 mm. The second comminution stage was performed by means of a Retsch SM300 equipment using hardmetal-made cutting tools (WC-based material). An internal cleaning of the machines and the collection of all the sub-aliquotes of the obtained powdered material was performed after each treatment.

**Sampling** Given the heterogeneous nature of the material, all fractions of the same type of sample were gathered into a single flat-bottom container and underwent homogenization and leveling. Sampling was made by coring with a glass cylindrical manual corer providing around 1g aliquots, applied to different regions of the sample (e.g. in the centre of each ideal quarter of material and in the geometrical centre of the sample as reported in Figure 1, in order to obtain representative sample aliquots for the subsequent treatments.

**Figure 1.** Schematic top-view of the WCPB shredded sample collected, homogenized and leveled in the flat-bottom container. Dotted lines (---) indicate the edges of the ideal quarters of the sample and circles (O) the coring points.

In particular, for each sample, the following aliquots were collected:

*a.* n. 5 1g aliquots, to be submitted to microwave mineralization in acid environment;

*b.* n. 1 20g aliquot, obtained by gathering twenty 1g corings, to be submitted to acid digestion under room conditions.

**Sample digestion** The aliquots referred to in point *a*, were weighed, then underwent microwave mineralization by introduction of the solid in TFM vessels containing a mixture of  $\text{HNO}_3$  (65%, 2 mL),  $\text{HCl}$  (37%, 6 mL) and  $\text{H}_2\text{O}_2$  (30%, 0.5 mL), and treatment in a Milestone Ethos 1 Microwave digester, equipped with an HPR1000/10S high pressure segmented rotor, an ATC-400CE automatic temperature control and a Terminal 640 with easyCONTROL software. The treatment was performed by applying

1  
2  
3 a microwave program consisting of two steps lasting 10 and 20 minutes, respectively, at  
4  
5  
6 a temperature of 220 °C and microwave power up to 1000 W. Differently, the bulky  
7  
8  
9 corings referred to in point *b*, were subjected to a prolonged digestion (24h) in a open  
10  
11  
12 flask at room temperature under magnetic bar stirring, preliminarily by slowly added  
13  
14  
15 HNO<sub>3</sub> 65% (250mL), and subsequently, after filtration on a glass funnel filter and  
16  
17  
18 collection of the leaching solution, by freshly prepared aqua-regia (HNO<sub>3</sub> conc. – HCl  
19  
20  
21 conc. 1:3 mixture, 200mL). At the end of the digestion process, each sample was  
22  
23  
24  
25 filtered off by the solid residue and the resulting clear solution properly diluted for the  
26  
27  
28 analysis with a 1% HNO<sub>3</sub> (aq) blank.  
29  
30  
31  
32  
33

34  
35 **ICP-AES characterization** The diluted solutions were analyzed by means of a Varian  
36  
37  
38 Liberty 200 Inductively Coupled Plasma-Atomic Emission Spectrometer (ICP-AES).  
39  
40  
41 Specifically, metals were detected with respect to 5-point calibration plots in the 1–50  
42  
43  
44 ppm range for copper and in the 1–10 ppm range for the other metals (correlation  
45  
46  
47 coefficient for single element calibration line > 0.9999). Elemental standards were  
48  
49  
50 prepared by dilution from 1000ppm mother solutions stabilized in HNO<sub>3</sub> 5% for Cu, Ag  
51  
52  
53 and base metals (except for Sn), and HCl 5% for Au, Pd and Sn.  
54

### NMs leaching on RAM #R#G#M sample

**RAMs milling** 200 g of RAMs of different origin were milled for 24 hours in a stainless steel jar by means of *hardmetal* balls ( $\varnothing$  6 mm, 1.4 Kg) in a planetary apparatus (4-stages Retsch mill, 300rpm) in the presence of Carbsyn 110 (250 mL). Carbsyn 110 is a non-flammable viscous liquid used as an auxiliary for the milling in ball mills. It belongs to the Carbsyn family of fluids which are safe-to-use, non-hazardous, odorless, non-flammable without a flash point and do not require an ATEX environment. At the end of the process, the slurry was separated by the *hardmetal* balls using sieves with grates of 4 mm. Then, Carbsyn was recovered by distillation and the milled sample collected and dried.

**Characterization of the sample** N. 4 aliquots of about 1.5 g each of RAM #R#G#M were sampled, digested under microwaves, and characterized for the most significant metals (Ni, Zn, Sn, Pb, Al, Cr, Mn, Fe, Au, Ag, Cu) by ICP-AES as described in paragraphs 2.1.2 - 2.1.4.

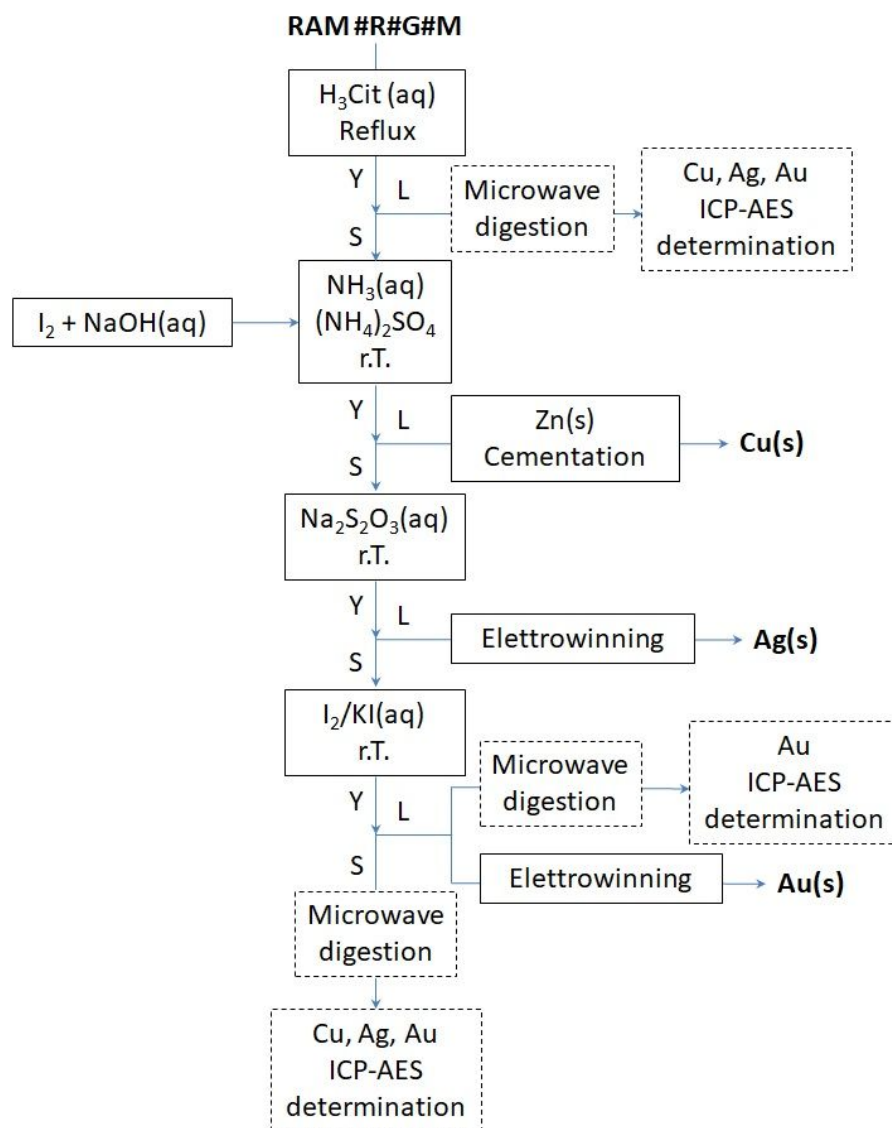

**Leaching and recovery processes** The selective NMs leaching and recovery procedure under study, was adapted from ref. 22 and applied to RAM #R#G#M sample

1  
2  
3 (selected sample of the project #Recovery #Green #Metal, see Acknowledgements) as  
4  
5  
6  
7 following detailed and summarized in Figure 2. 10g of sample were reacted with 300mL  
8  
9  
10 of citric acid ( $\text{H}_3\text{Cit}$ ) 3M at the refluxing temperature (100-120°C) for 48 hours. The  
11  
12  
13  
14 solution turned from colorless to light green and gaseous  $\text{H}_2$  developed when the  
15  
16  
17 reaction went off. Due to the  $\text{H}_2$  production during the reaction, an inert atmosphere is  
18  
19  
20 desirable for safety reasons. Afterwards, the cleared and reddish solid residue was  
21  
22  
23  
24 separated from the solution by filtration under vacuum, washed by water and then by  
25  
26  
27 acetone, dried and weighted. The leaching solution underwent digestion and chemical  
28  
29  
30 analysis for copper, gold and silver determination as described in 2.1.2 - 2.1.4. Base  
31  
32  
33 metals content was estimated by weight loss. The dried sample was then reacted, at  
34  
35  
36 room temperature under magnetic bar stirring, with  $\text{NH}_3$  (aq) 33% (15 mL) in the  
37  
38  
39 presence of  $(\text{NH}_4)_2\text{SO}_4$  (13.0 g). A solution prepared dissolving  $\text{I}_2$  (25 g) in  $\text{NaOH}$  (aq)  
40  
41  
42 (1.5 M, 150 mL) was added dropwise to the mixture, readily turning the solution from  
43  
44  
45 colorless to blue. After 48 hours the solid residue was filtered. The procedure was  
46  
47  
48 repeated other 2 times (24 hours cycles) until the solution stop to turn to the blue.  
49  
50  
51  
52  
53  
54  
55  
56 During the reaction, the yellowish  $\text{AgI}$  precipitation occurred. All the obtained leaching  
57  
58  
59  
60

1  
2  
3 solutions were gathered in the same flask for Cu recovery. The solid residue, was then  
4  
5  
6 leached by a  $\text{Na}_2\text{S}_2\text{O}_3$  aqueous solution (0.06 M, 35 mL) at room temperature and the  
7  
8  
9 leachate filtered and collected for silver recovery. Finally the last solid residue were  
10  
11  
12 leached by a  $\text{I}_2$  (1.04 g)/KI (3.68 g) water solution (80mL) for 30 minutes at room  
13  
14  
15  
16 temperature under stirring. The solid residue was filtered off the solution, digested under  
17  
18  
19 microwaves and analyzed for unreacted NMs (see 2.1.2-2.1.4). The leaching solution  
20  
21  
22 was collected, diluted and directly analyzed by ICP-AES for gold. Cu(s) recovery was  
23  
24  
25 performed from the leaching solution by addition of an excess of Zn metal (5 g, powder,  
26  
27  
28 20 mesh, freshly washed by HCl dil.) under stirring at room temperature. Zn grains  
29  
30  
31 slowly dissolved, red copper flakes precipitated and the blue solution cleared when the  
32  
33  
34 cementation reaction went on. The solution was separated from the solid by decantation  
35  
36  
37 and Cu metal was recovered, washed three times by HCl dil., then by water, dried and  
38  
39  
40 weighted (yield: 70%). Ag(s) and Au(s) recovery were performed by electrowinning from  
41  
42  
43 the thiosulfate and triiodide leaching solutions, respectively. Electrowinning experiments  
44  
45  
46 were performed by an apparatus constituted by two metallic electrodes (Pt-wire for the  
47  
48  
49 anode and Cu-wire for the cathode) connected, to their respective ends, with an  
50

2  
3 external electron supply (Thurlby Thandar Instruments, mod. PL 310) which drives the  
4  
5  
6  
7 process (see Scheme 5 for the cell). Ag(s) and Au(s) recovery yields: 92% and 65%,  
8  
9  
10 respectively, by applying 2.50 mV for 1 hour without adding any support electrolyte to  
11  
12  
13 the cell. Due to the technological limitations of the available apparatus, the  
14  
15  
16  
17 electrowinning processes were not optimized. Nevertheless, performed experiments  
18  
19  
20 were suitable to demonstrate the feasibility of the metal recovery by electrochemical

## Results and discussion

### Materials characterization and test specimen selection

WPCBs were selected as target WEEE for the activity, due to their wide availability and “richness” in terms of NMs, mainly gold, content. Different typologies of WPCBs

1  
2  
3 currently in use were hence collected and characterized in terms of NMs content as  
4  
5  
6  
7 described in the following. The accurate characterization of such a complex materials is  
8  
9  
10 a challenging issue, requiring great control in operations, representative samplings,  
11  
12  
13 correct treatments of materials and quantitative chemical analysis data interpretation.  
14  
15  
16  
17 Quite a few papers report WPCBs composition,<sup>23,24,13,15</sup> but a further effort sounded  
18  
19  
20 useful to build a robust database of strictly controlled data focusing on the different kind  
21  
22  
23  
24 of PCBs available on the market.  
25  
26  
27

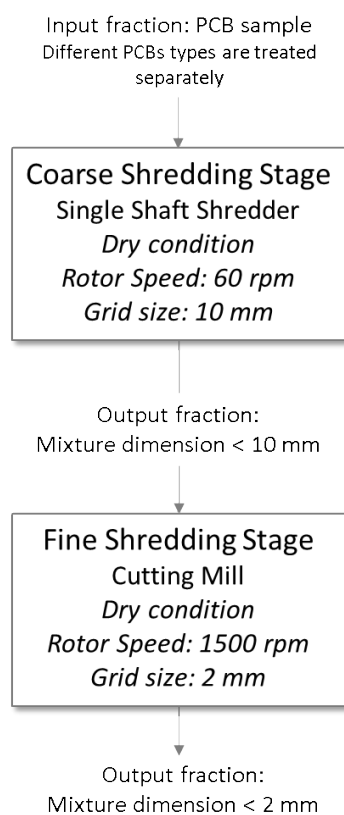

28 **Physical processes** Table 1 summarizes the number, weight and typologies of  
29  
30  
31 WPCBs supplied by companies underwent comminution and the amount of powdered  
32  
33  
34 sample obtained through mechanical treatments. Size-reduction treatments were  
35  
36  
37 performed by the STIIMA-CNR Demanufacturing Pilot Plant – Cell 3 – Mechanical  
38  
39  
40  
41 Recycling, are summarized in Figure 3. They consisted in a preliminary comminution  
42  
43  
44 with a single shaft shredder which provided a 1st stage shredded material (average  
45  
46  
47 size: 10 mm) which underwent a further shredding process with cutting mill (rotor speed:  
48  
49  
50 1500 rpm), providing a thinner powdered sample (2nd stage material, sieve grates = 2  
51  
52  
53  
54  
55  
56 mm).  
57  
58  
59  
60

**Table 1.** List of PCB samples underwent comminution.

Typology	n.	Starting weight	Weight after shredding		Weight loss (%)	Elements removed
			1 <sup>st</sup> stage (g)	2 <sup>nd</sup> stage (g)		

			(g)				before shredding
DVD/CD players	7	220.0	220.0	214.8	2.1		Motors and rotating supports (334g)
PCB

**Figure 3.** Schematic view of mechanical size-reduction treatments.

The size-reduction treatments were performed under dry conditions after the removal of some minor components not containing NMs (i.e. motor and rotating supports, fasteners and ferrous parts), to avoid machine jamming and damages. In order to obtain the most accurate results, all available WPCBs for each different typology were gathered and submitted to comminution, preventing material loss as much as possible

1  
2  
3 (maximum materials loss accounted for: 2.9%). Given the heterogeneous nature of the  
4  
5  
6  
7 samples, they were treated separately and an internal cleaning of the machine was  
8  
9  
10 performed by using a vacuum cleaner after each treatment, in order to avoid loss of  
11  
12  
13 precious materials and samples contamination. Moreover, further separation  
14  
15  
16  
17 procedures, addressed to concentrate the metallic value into a fraction, were avoided in  
18  
19  
20 order to limit the loss of NMs which is typically observed during eddy current and  
21  
22  
23 magnetic separations. Indeed, NMs, in particular gold, often consist of a very thin layer  
24  
25  
26  
27 paired with magnetic elements like nickel. By shredding, NMs are reduced to a very thin  
28  
29  
30  
31 powder which can be dispersed in the separation phases. Typically, it can follow nickel  
32  
33  
34  
35 in magnetic separations. The whole amount of the shredded samples (2nd stage out-  
36  
37  
38  
39 put) was then collected and stored to be following submitted to representative sampling  
40  
41  
42 and characterization.

43  
44  
45 **Sampling and characterization** In order to obtain accurate results, the following  
46  
47  
48 operations were carefully performed to pursue sample representativeness as much as  
49  
50  
51 possible. The whole amount of comminuted sample for each WPCB typology was  
52  
53  
54  
55 collected in a flat-bottom box, homogenized and leveled. Then it was sampled by  
56  
57  
58  
59  
60

1  
2  
3 manual coring in order to overcome material layering. Due to the really heterogeneous  
4  
5  
6  
7 nature of the sample, 5 different samplings about 1g each were performed by manual  
8  
9  
10 coring in different areas of the sample as schematized in Figure 1. The different aliquots  
11  
12  
13  
14 were then digested by a mixture of  $\text{HNO}_3$ ,  $\text{HCl}$  and  $\text{H}_2\text{O}_2$  under microwave oven  
15  
16  
17 conditions as detailed in 2.1.3 section. In order to compare the analytical results  
18  
19  
20 obtained by these 5 low amount aliquots (common microwave digestors can operates  
21  
22  
23 just on small amount of material) with a bulkier one, a larger amount (20g) of material  
24  
25  
26  
27 was then massively sampled and leached in two steps by means of an excess of  $\text{HNO}_3$   
28  
29  
30  
31 65% solution, then with aqua-regia on the solid residue, both under stirring at room  
32  
33  
34 conditions for 24 hours. Finally all the digested fractions were filtered and the solutions  
35  
36  
37 properly diluted by a 1%  $\text{HNO}_3$  blank and measured for Au, Cu, Ag and Pd over five-  
38  
39  
40  
41 points calibration plots (see 2.1.4). For clarity, Figure 4 summarizes the different  
42  
43  
44 sampling and treatments applied on each WPCB sample, up to the ICP-AES  
45  
46  
47 characterization. The results obtained for the two kind of sampling and treatments  
48  
49  
50  
51 mostly agreed.  
52  
53  
54  
55  
56  
57  
58  
59  
60

**Figure 4.** Summary of sampling, digestion and NM-analysis of the shredded WPCBs.

Table 2 summarizes the metal content percentages, calculated as the weighted average of the measured values by the different analyzed aliquots. In agreement with the literature, the results identified RAMs and mobile phone PCBs as the “richest” classes of PCBs, while TV PCBs as the “poorest” in term of NMs content. Because of their NMs content and sample availability by companies, waste RAMs were selected as target WPCBs for the present study.

**Table 2.** NMs content of different typologies of WPCBs determined by ICP-AES measurements.

WPCB sample	NMs content - %(SD)			
	Pd	Au	Ag	Cu
DVD/CD players	<0.01*	0.01(±0.0 1)	0.08(±0.0 5)	16.2(±4. 4)
NIC	<0.01*	0.02(±0.0 1)	0.03(±0.0 1)	19.1(±2. 3)
RAM white fingers	0.04(±0.0 3)	0.03(±0.0 1)	0.10(±0.0 6)	16.6(±1. 9)
RAM gold fingers	0.01(±0.0 1)	0.07(±0.0 1)	0.05(±0.0 1)	17.1(±1. 2)
Hard drive	0.02(±0.0 2)	0.03(±0.0 1)	0.06(±0.0 5)	23.6(±4. 9)

Mother boards	<0.01*	0.01(±0.0 1)	0.04(±0.0 2)	26.7(±5. 4)
TV	<0.01*	<0.01*	0.03(±0.0 1)	13.0(±7. 4)
Mobile phone	0.06(±0.0 2)	0.07(±0.0 1)	0.14(±0.0 5)	33.8(±1. 1)

### RAM #R#G#M sample as a case study

**Sample comminution and characterization** RAM #R#G#M sample is a coarse material obtained by a planetary ball milling of a selection of RAMs (mix, 200g) for 24 hours in a stainless steel jar by means of *hardmetal* balls ( $\varnothing$  6 mm, 1.4Kg) in the presence of Carbsyn, as detailed in 2.2.1 (Figure 5).

**Figure 5.** Preparation of the RAM #R#G#M sample.  $i = 24\text{h}$ , room temperature; stainless steel jar planetary apparatus: 4-stages mill, 300 rpm; *hardmetal* balls  $\varnothing = 6$  mm, weight = 1.4 Kg; solvent: Carbsyn, 250 mL.

1  
2  
3 Carbsyn, due to its low flammability, was used as milling media with the aim to  
4  
5  
6  
7 dissipate the heat produced during the milling process. Negligible erosion phenomena  
8  
9  
10 on the *hardmetal* balls were observed, with a weight loss of 5 g during the 24 hours  
11  
12  
13 treatment (weight loss = 0.35%). The obtained RAM #R#G#M sample is characterized  
14  
15  
16  
17 by a wide particle size dispersion (diameters spanning from <1mm to several mm,  
18  
19  
20 where 106g  $\varnothing$  <2mm and 94g  $\varnothing$ >2mm) and by the presence of a huge amount of  
21  
22  
23 composite vitreous-plastic support material (around 70% w/w). Four portions of the  
24  
25  
26  
27 described material were sampled and characterized for gold, copper, silver and  
28  
29  
30 palladium, and for the main base metals, by means of ICP-AES analysis, on the  
31  
32  
33  
34 solutions prepared by microwave-assisted digestion as previously described.  
35  
36  
37

38  
39 Table 3 summarizes the metal content of the sample, which almost agreed, for NMs,  
40  
41  
42 with the previous RAMs characterization and with literature values for the other metals  
43  
44  
45 (Table 2).<sup>13,15</sup>

Sn	1.9 ( $\pm 0.3$ )

\*Below Limit of Detection (LoD)

1  
2  
3  
4 The relatively high standard deviation values are representative of the really  
5  
6  
7 heterogeneous nature of the sample and highlight how the sampling might affect the  
8  
9  
10 accuracy, in terms of precision, of the results. For comparison purposes, the reference  
11  
12  
13 sample A, obtained as the output of a mechanical de-processing plant, where a  
14  
15  
16 selection of WPCBs and small electronic equipments were shredded and submitted to  
17  
18  
19 mechanical pre-treatments in order to separate the incoming mixture into homogeneous  
20  
21  
22 particle flows with a high concentration of aluminum, ferrous metals, vitreous-plastic  
23  
24  
25 materials and non-ferrous metals, was taken into consideration. A comparison between  
26  
27  
28 the RAM #R#G#M sample and the reference sample A is reported in Table 4.  
29  
30  
31  
32  
33  
34

35 **Table 4.** Metal content and main features of the RAM #R#G#M and the reference  
36  
37  
38 Sample A.  
39  
40  
41

Metal content (% w/w)			Sample features	
RAM #R#G#M	Ref.		RAM	Ref.
<i>a</i>	<i>b</i>	Sample A	#R#G#M	Sample A

Au	0.08	0.3	0.01		
Cu	15	49	79		
Ag	0.04	0.1	0.06	Coarse material from RAMs	Thin metallic powder from mixed WEEE
Ni	4.2	14	0.5	Metallic fraction: ~ 30% of the sample	Deprived by ferrous and non-metallic materials
Fe	7	23		Presence of ferrous and vitreous-plastic materials (~ 70%)	Costly treatments and equipments
Al	1.4	4.6			
Cr	-*	-*	1		
Mn	0.06	0.2		Low cost pre-treatments	Huge loss of valued materials
Pb	0.8	3	7		
Sn	1.9	6.2	10	Limited loss of materials	
Zn	-*	-*	2		

<sup>a</sup>On the whole sample; <sup>b</sup>On the metal fraction. \*Below LoD.

The comparison between the two samples highlights that, as expected, RAM #R#G#M sample, deriving from a selection of high value WPCBs, is the “richest” in terms of NMs content with respect to sample A, obtained instead from mixed small EEE. At the same time the former contains a lower percentage of copper and lead. Furthermore, being the separation phase avoided, light metals (Al) and ferrous (Fe, Ni) and vitreous plastic materials are still present.

1  
2  
3  
4 **Selective leaching and NM recovery** A portion of the RAM #R#G#M sample underwent  
5  
6  
7 the full leaching & recovery procedure previously applied to the reference sample A.<sup>22</sup>  
8  
9  
10 The main focuses of the experiment on the RAM #R#G#M sample were intended to  
11  
12  
13  
14 point out: i) how the effectiveness in NMs recovery, in terms of yields and metal  
15  
16  
17 leaching times and conditions would be affected by the heterogeneous nature of the  
18  
19  
20  
21 sample; ii) whether the process would occur selectively as observed in the previous  
22  
23  
24 case or if it would be affected by formation of by-products. The process, summarized in  
25  
26

		5:1	RGM	0.08		0.5		

<sup>a</sup>Expected leaching time on the basis of previous results; <sup>b</sup>Experimental observation time; <sup>c</sup>See refs. <sup>25</sup> and <sup>26</sup>.

In Leach 1, 10g of RAM #R#G#M were reacted firstly with approximately 300mL of a H<sub>3</sub>Cit water solution (3M) (Liquid/Solid ratio, L/S=30) under stirring and reflux for 48 hours for base metal leaching with consequent formation of base metals citrate complexes and gaseous H<sub>2</sub> development. The solution turns from colorless to greenish when the reaction went off. Afterwards, the solid residue was separated from the solution by filtration, washed by water and then by acetone and dried. The found weight loss (~30%) of the solid sample was compatible with the full leaching of base metals plus a slight amount of copper, in agreement with the green color of the solution.

1  
2  
3  
4 Quantitative copper determination onto the leaching solution found that 0.37g of Cu  
5  
6  
7 (representing the 3.7% of the sample and the 25% of the whole Cu content of the  
8  
9  
10 sample) dissolved in those conditions. On the basis of this result, in order to obtain  
11  
12  
13  
14 higher selectivity, shorter leaching times and/or working under inert atmosphere might  
15  
16  
17 be advisable. In Leach 2, the dried sample was reacted with a NH<sub>3</sub> 33% water solution  
18  
19  
20 in the presence of (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> (L/S ≅ 2), slowly adding a solution prepared by dissolving  
21  
22  
23 I<sub>2</sub> in aqueous NaOH 1.5 M, at room temperature (final L/S ≅ 20). The solution promptly  
24  
25  
26  
27 turned from colorless to blue as the oxidizing IO<sub>3</sub><sup>-</sup> specie was added to the mixture and  
28  
29  
30  
31 the copper leaching went on forming the [Cu(NH<sub>3</sub>)<sub>4</sub>]<sup>2+</sup> complex, as summarized by the  
32  
33  
34  
35 following equations:

46  
47  
48  
49 After 48 hours, the solid residue was filtered and the solution collected for copper  
50  
51  
52 recovery. To ascertain that complete copper dissolution was achieved, the procedure  
53  
54  
55  
56 was repeated on the solid residue until a colourless solution appeared. The whole  
57  
58  
59  
60

1  
2  
3  
4 copper dissolution was achieved in approximately 96 hours. Meanwhile, the silver  
5  
6  
7 leaching and precipitation of AgI occurred by the reaction:

11  
12  
13  
14 All the copper-containing solutions were gathered and copper was recovered from the  
15  
16  
17 solution by cementation with an excess of Zn metal at room temperature obtaining a  
18  
19  
20  
21 70% Cu metal recovery yield by weight after washing the red Cu flakes by HCl dil.

22  
23  
24 (Figure 7).

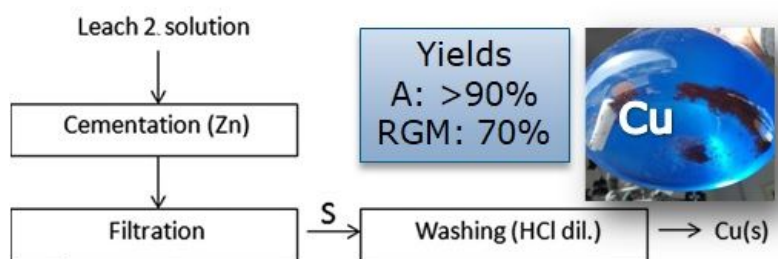

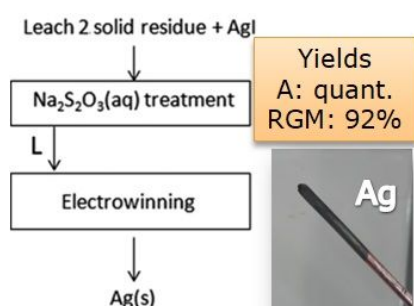

Figure 7. Leach 2 solution: copper recovery processes. Cu recovery yields for reference sample A (A) and RAM #R#G#M (RGM). S = solid phase.

It is noteworthy that the copper leaching time for this sample was expected to be 2- times shorter than that found. This finding is reasonable considering copper is the most abundant among the metals in the sample and also its recovery is the most affected by

1  
2  
3 the coarse nature of the sample due to its inclusion into the vitreous-plastic support  
4  
5  
6  
7 matrix (being the main metal used for circuit pathways). Moreover, in contacts and  
8  
9  
10 connections, it is covered by gold.

11  
12  
13  
14 Figure 8 summarizes silver metal recovering processes.

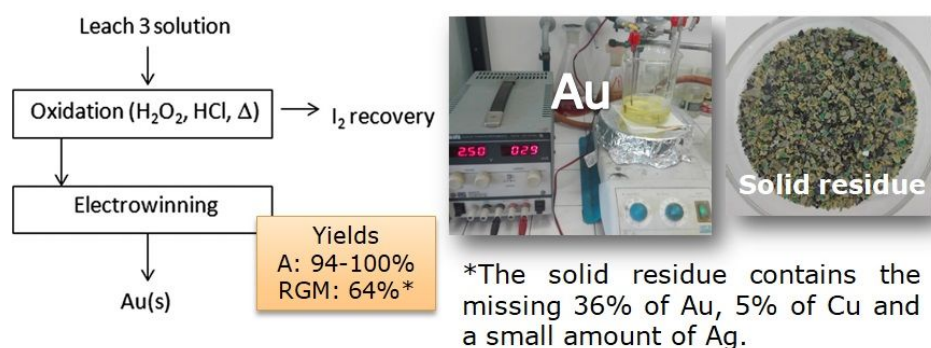

27 **Figure 8.** Leach 2 solid residue: silver recovery process. Ag(s) recovery yields for  
28  
29 reference sample A (A) and RAM #R#G#M (RGM). L = liquid phase.

30  
31  
32  
33  
34  
35  
36 AgI was leached away from the Leach 2 solid residue by washing it with a  $\text{Na}_2\text{S}_2\text{O}_3$   
37  
38 water solution at room temperature. After filtration, silver metal was recovered in high  
39  
40 yield (92%) from the leaching solution containing the  $[\text{Ag}(\text{S}_2\text{O}_3)_2]^{3-}$  complex, by  
41  
42  
43 electrowinning as a coating deposition on a Cu cathode (see details in 2.2.3). Finally,  
44  
45  
46  
47  
48  
49  
50 the solid residue underwent gold leaching by using 80mL of a water solution containing  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

$I_2/I^-$  ( $E^\circ(I_3^-/I^-) = +0.54V$ ) in a 1:5 molar ratio (4.1 and 22.2 mmol, respectively), for 30' at room temperature under stirring following the reaction:

After leaching,  $H_2O_2$ –HCl were added to the solution in order to oxidize iodide and recover  $I_2$  (Figure 9). Metal analysis on the leaching solution showed that a 64% gold leaching yield was found for RAM #R#G#M sample in the applied experimental conditions with respect to the almost quantitative occurred in the case of reference sample A. This data was in agreement with the amount of gold deposited by electrowinning from the resulting chloride solution on a copper wire working as cathode.

**Figure 9.** Leach 3 solution: gold recovery process. Au(s) recovery yields for reference sample A (A) and RAM #R#G#M (RGM).

1  
2  
3  
4 Nevertheless, wide improvements in gold reclamation are expected by prolonging the  
5  
6  
7 leaching time for the “richest” last cited sample (gold content: sample A = 0.01%; RGM  
8  
9  
10 = 0.08%). In agreement, the missing 36% of gold was found in the final solid residue.  
11  
12  
13  
14 Beside gold, 5% of copper and a small amount of silver were found in the final solid  
15  
16  
17 residue as well, highlighting that, according to the previous findings, copper remains  
18  
19  
20  
21 partially included in the support matrix and it is exposed gradually to the leaching.  
22  
23

24 No interfering by-products were isolated and/or identified along the whole leaching  
25  
26  
27 and recovery process.  
28  
29  
30

31 A comparison between the proposed method and the more conventional ones, e.g.  
32  
33  
34 based on the direct use of  $\text{HNO}_3$  and/or aqua regia solutions,<sup>27</sup> highlights that the use of  
35  
36  
37 the selected leaching agents promote a slightly less efficient, in terms of recovering  
38  
39  
40 times and rates, but more selective and sustainable NMs recovery. Indeed, besides the  
41  
42  
43 slight loss in efficiency which can be faced improving the degree of comminution and  
44  
45  
46 prolonging the leaching times, the method described here pursues and obtains the  
47  
48  
49 phase-by-phase dissolution and recovery of metals using leaching agents specifically  
50  
51  
52 selected for coupling the highest affinity towards each metal class with the lower  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 environmental impact. At the contrary, the more aggressive conventional methods,  
4  
5  
6  
7 beside a high efficiency of the leaching phase (potentially nearly quantitative in short  
8  
9  
10 times), achieve no or very low selectivity (HNO<sub>3</sub> dissolves all the metals with standard  
11  
12  
13 reduction potential <0.96V, then including copper and silver; aqua regia dissolves gold  
14  
15  
16 as well) which heavily affects the following metal recovery phase, produce abundant  
17  
18  
19  
20  
21 toxic emissions (mainly NO<sub>x</sub>, besides other gaseous by-products), related to the strong  
22  
23  
24 oxidative action of HNO<sub>3</sub> and or Cl<sub>2</sub> towards metals and plastics, and wastewaters,  
25  
26  
27  
28 which require strict industrial set up, risk assessment and qualified staff, for being  
29  
30  
31 managed.  
32  
33

## 34 **Conclusions**

35  
36  
37  
38  
39 As well-known, hydrometallurgical methods clearly benefit from prior comminution and  
40  
41 separation, able to reduce bulk volume, to expose a greater surface area of contained metals to  
42  
43 the leaching and to limit interfering reactions. This important pre-treatment becomes more  
44  
45 helpful for improving effectiveness when selective non-aggressive reactants are used to meet  
46  
47 sustainability requirements, as shown by the preliminary results here described. Nevertheless,  
48  
49 these treatments remain the most expensive and technologically concerning part of the whole  
50  
51 recovery process pointing out the need to balance the comminution and separation effort with the  
52  
53 following leaching and recovery processes. The robustness of an innovative NM recovery  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 method from WPCBs coupling “greenness” with effectiveness, was demonstrated by its  
4 application on a coarse sample of shredded RAMs. Indeed, though the limited low-cost  
5 mechanical pre-treatments underwent by the sample, satisfactory NMs recovery yields (Cu 70%,  
6 Ag 92%, Au 64%) are found applying an effective three phases leaching process where i) a  
7 refluxing citric acid aqueous solution achieves base metals leaching in 48 hours; ii) ammonia in  
8 oxidizing environment operates Cu and Ag leaching and separation in one pot in almost 96  
9 hours; and iii) a triiodide aqueous solution dissolves gold in about 30’; followed by a  
10 cementation or electrochemical deposition of the different NMs. This process provides a clean  
11 separation with limited by-products formation using safe and recyclable reagents in mild  
12 conditions. Consequently, it is worth noting the coarse nature of the sample does not seem  
13 jeopardize the whole metal recovery process. A further effort in combining the pre-treatment set  
14 up with the subsequent leaching processes would help in obtaining the optimal conditions to  
15 meet the effectiveness and sustainability required for practical application as aimed by green  
16 chemistry & engineering principles, and open the way to the scale-up phase on a pilot plant.

## TOC &amp; SYNOPSIS

Towards circular economy: application of a “green” NMs recovery process from WPCBs with high metal recovery rate and low-cost pre-treatments.
