Bismuth is recognized as a Critical Raw Material by the EU Commission and it is found in many ore deposits across the world. In Southwestern (SWS) and Southeastern (SES) Sardinia, Bi-minerals are commonly found in two main groups of ore deposit: 1) late Variscan granite-related orebodies including greisens, W-Mo(-Sn) HT hydrothermal veins, skarns and hornfelses; and 2) late- to post-Variscan five-element (Ni-Co-As-Bi-Ag) LT hydrothermal veins.

In the first group, greisens (Flumini Binu prospect, SWS) and HT hydrothermal W-Mo(-Sn) veins (Perd'e Pibera mine and Togoro prospect, SWS; Perda Majori-Brunco Spangas prospects, SES) typically host native Bi, bismuthinite and, subordinately, Pb-Ag-Bi-sulfosalts interstitial to molybdenite and/or scattered in the quartz-feldspar(-fluorite-topaz) gangue. Locally, maldonite (Au<sub>2</sub>Bi), Bi-tellurides (hedleyite Bi<sub>7</sub>Te<sub>3</sub>, and Bi<sub>2</sub>Te) and probable russellite (Bi<sub>2</sub>WO<sub>6</sub>) are abundant in wolframite-rich veins (Togoro prospect), associated with native Au. Small grains of native Bi have also been found in some poorly mineralized garnet-vesuvianite-epidote calc-silicate hornfelses (Domus De Maria, SWS). Besides native Bi and bismuthinite, skarn orebodies frequently host wider assemblages consisting of Bi-Pb-Ag-Cu-sulfosalts intergrowths, once again associated with wolframates (scheelite at Monte Tamara prospect and Sa Marchesa mine, SWS) and molybdenite (Monte Tamara, Sa Marchesa and Morettu prospect, SWS). As a reference, the Monte Tamara assemblage includes "phase 88.6" (Cu<sub>0.33</sub>Pb<sub>0.33</sub>Bi<sub>7.67</sub>S<sub>12</sub>), pekoite (PbCuBi<sub>11</sub>S<sub>16</sub>Se<sub>2</sub>), salzburgite-paarite (Cu<sub>1.58-1.67</sub>Fe<sup>2+</sup><sub>0.03-0.01</sub>Pb<sub>1.65-1.72</sub>Bi<sub>6.38-6.3</sub>S<sub>12-12.06</sub>), gustavite (PbAgBi<sub>3</sub>S<sub>6</sub>) xilingolite-lillianite (Pb<sub>3</sub>Bi<sub>2</sub>S<sub>6</sub>), cosalite (Pb<sub>2</sub>Bi<sub>2</sub>S<sub>6</sub>), berryite (Cu<sub>3</sub>Ag<sub>2</sub>Pb<sub>3</sub>Bi<sub>7</sub>S<sub>16</sub>), ourayite (Pb<sub>4</sub>Ag<sub>3</sub>Bi<sub>5</sub>S<sub>13</sub>) and cupropavonite (Cu<sub>0.9</sub>Ag<sub>0.5</sub>Pb<sub>0.6</sub>Bi<sub>2.5</sub>S<sub>5</sub>), identified by means of EPMA analyses. Moreover, since high Bi(-Ag-Te) contents have been detected in sulfides (sphalerite, galena, arsenopyrite), micro-inclusions of -sulfosalts and/or -tellurides may also occur. In the same area, wittichenite ((Bi,Cu)<sub>2</sub>S<sub>3</sub>) and hammariite (Pb<sub>2</sub>Cu<sub>2</sub>Bi<sub>4</sub>S<sub>9</sub>) have been previously identified, while schapbachite (AgBiS<sub>2</sub>) has been reported at the Sa Marchesa mine.

The second group of Bi-bearing orebodies includes the five-element veins of the Arburès district (Pira Inferida, Acqua Is Prunas and Sa Menga mines, SWS), where native Bi and bismuthinite typically occur at the core of Ni-Co arsenides-sulfarsenides (e.g. nickeline and gersdorffite-cobaltite) concentric growths.

Therefore, the strong affinity of bismuth for granite-related W-Mo(-Sn) deposits of Southern

Sardinia indicates that the late-Variscan (Early Permian) granites represent its main metallogenic source. However, the formation of such diverse Bi-minerals assemblages is seemingly controlled by local-scale conditions. In skarn ores, the Bi-Pb-Ag-Cu-sulfosalts intergrowths formed during the sulfide stages, apparently after the interaction between primary Bi-phases and Pb-Ag-Cu-bearing hydrothermal fluids and under oscillatory variations of metals availability and stability. Conversely, in W-Mo(-Sn) hydrothermal veins and greisens, where sulfides are apparently more scarce, the array of Bi-phases is usually more limited. Furthermore, field and analytical data point towards a selective remobilization of bismuth from the primary native and -tellurides assemblage of HT wolframite-quartz veins (Togoro, SWS) by late cross-cutting LT five-element veins, suggesting that multiple, spaced over time hydrothermal-veining events occurred in the same area.

In conclusion, bismuth and related mineral phases could serve as important markers, providing useful qualitative indications regarding the source of metals, the ore-forming processes and the relationships between different ore deposits at the district-scale.
